Appointments.—The following are among the appointments open to past and present students of this school in connexion with its arrangements for clinical tuition: two pathological registrars, at £100 and £50 per annum; one medical registrar at £150; a cardiographic registrar, at £150; a director of the clinical laboratory at £400, and two assistants at £350 and £300; four chief assistants to medical units, each at £300; four chief assistants to surgical units, £250; chief assistant to neuro-surgical service, £350; chief assistant to orthopaedic department, £250; clinical tutor to orthopaedics, £35; medical registrar to out-patient department, £150; assistant surgical officers, aural department at £35; seven anaesthetists from £75 to £125 each; three anaesthetists at central branch, £25 to £100; one resident medical officer, one year, £200; one resident clinical pathologist, £100; one resident surgical officer, one year, £200; senior house-surgeon for central branch, £150; one resident casualty officer, £150; one resident medical officer at the Convalescent Hospital at Cheadle, £250; two assistant medical officers to radiological department, £400 and £200; medical officers, physiotherapeutic department, £150; assistant medical officer, £100; chief assistant, gynaecological department, £70; assistant to the dermatological department, £35; two medical officers, out-patient department, each £105; sixteen assistant surgical officers to dental department, £35; four technical assistants for laboratory work, £200; clinical assistant to aural out-patient department, £35; twelve house-surgeons and eight house-physicians, appointed during the year for periods of six months, at a salary of £50 per annum. Resident officers are appointed to the gynaecological, the eye, and the ear and throat departments every three months. Clinical clerks and surgical dressers are appointed to the various departments of the hospital every three months. Non-resident clinical assistantships for qualified medical men and women, tenable for six months, at an honorarium of £35.

Entrance and other Scholarships.—The following are among the scholarships obtainable by students of the school: Rogers and Seaton Scholarships in Arts (in alternate years), £40 per annum, tenable for two years. Three Hulme Scholarships, tenable for three years, of £35, one being awarded annually for proficiency in subjects of general education. Two James Gaskill Scholarships of £35, tenable for two years, one being awarded annually for proficiency in the branches of mechanics and chemistry. A Dora Muir Scholarship, £30 per annum, tenable for three years, and open to the competition of women students only. This is awarded triennially. Sir J. P. Kay-Shuttleworth Scholarship, £30 per annum, tenable for three years, awarded triennially, open to the competition of scholars from Sedbergh School, Giggleswick School, and Burnley Grammar School; subjects—mathematics, chemistry, and

mechanics. Dreschfeld Memorial Scholarship, value £20, tenable for two years and awarded triennially on the result of the Entrance Examination. John Russell Medical Entrance Scholarship, awarded annually, value £45. Two Dauntesey Junior Medical Scholarships, value £50 each, tenable for one year, for candidates who have not commenced the second year of study leading to a medical qualification; subjects—chemistry, physics, botany, and zoology. One Dauntesey Senior Medical Scholarship, £50 for one year, awarded on results of Second M.B. Examination. Two Entrance Scholarships in medicine, value 160 guineas, awarded annually for proficiency in arts or science respectively. Tom Jones Exhibition in anatomy, £25, offered annually. A Robert Platt Physiological Scholarship of £90, tenable for one year. A Leech Fellowship of £100 for original research after graduation. A Graduate Research Scholarship in medicine, value £70, tenable for one year, awarded annually for proficiency shown at Final M.B. Examination. Two Dumville Surgical Prizes, each value £15, awarded annually at graduation. The Tom Jones Memorial Surgical Fellowship, value £105, tenable for one year, usually awarded annually. The Turner Medical Prizes, value 10 guineas each, awarded annually for proficiency in certain subjects of the Final M.B., Ch.B. Examination. The John Henry Agnew Prize of £30, awarded annually for proficiency in the diseases of children. The Ashby Memorial Scholarship, tenable for one year (£100), for research in the diseases of children; offered triennially, Sidney Renshaw Prizes in physiology: offered annually (£10 and £20). Wild prize in pharmacology (£10). The John Henry Agnew Fellowship in diseases of children, £120, offered triennially. Eliza Marple Holt Postgraduate Medical Scholarship for Women, £60 for one year, offered biennially. The details and regulations of the Dickinson Scholarships—(1) for anatomy, (2) for pathology, (3) Research Scholarship in surgery, and (4) Travelling Scholarship in medicine—may be obtained from the Secretary to the Trustees. The Morrison Watson Fellowship for research in anatomy is offered annually, value £150; also the Sheridan Delepine Fellowship in preventive medicine, value £300, is offered biennially. The Sam Gamble Scholarships—the trustees are prepared to award four scholarships of not more than £40 per annum, to women students who have passed the First M.B. Examination; the conditions can be obtained from the Registrar. The Knight Fellowship of £150, offered triennially for the encouragement of the study of factors concerned in the development of the symptoms of mental disturbance —*open to competition of graduates of this or any approved* university. Pilkington Fellowship in Cancer research £300 for one year.

Fees.—The composition fee for the university course in medicine is 114 guineas, payable in four instalments of 28½ guineas, but this sum does not include the fee to cover the work required for the First M.B. Examination. This is £42, payable in one sum. Hospital fees are additional, and usually amount to about 90 guineas.

A prospectus and further information about the school and scholarships may be obtained from the Registrar.

Sheffield

In this city the Medical School is one of the departments of the university, being conducted and controlled by its Medical Faculty, and occupying practically the entire north wing of the quadrangle of the university buildings overlooking Weston Park. The laboratories and lecture rooms connected with the subjects of the first and second examinations—namely, chemistry, physics, biology, anatomy, and physiology—are, both as regards structural arrangement and scientific equipment, on the most modern and complete lines.

For students of pathology and bacteriology there are laboratories replete with everything necessary for the most advanced work, and a large pathological museum, which is open daily. In addition, there is a large library and reading room. There are a number of recreation, athletic, and other societies, all under the management of an annually elected students' representative council, and large and comfortable common rooms for both men and women students. Thanks to the generosity of Alderman J. G. Graves there is a new and well-equipped Union building in close proximity to the university which affords ample facilities for the various student social activities.

There is ample hostel accommodation for both men and women students. In the university and in the Union buildings there are refectories open to all students of the school. A university journal is published each term, and the Medical School also publishes a journal. The ordinary clinical work of the school is done at the Royal Infirmary and Royal Hospital, which have amalgamated for the purpose of clinical instruction, and provide over 800 beds for medical, surgical, and special cases, including diseases of the eye.

In addition, the Royal Infirmary has special departments for the treatment of diseases of the skin and ear, with beds assigned to them; whilst at the Royal Hospital there are special out-patient departments for diseases of the throat, ear, skin, orthopaedics, and mental diseases. The medical and surgical staffs attend daily, and give clinical instruction in the wards and out-patient rooms. Clinical lectures in medicine and surgery are given weekly. Instruction in the practical administration of anaesthetics is given at either institution by the anaesthetists, and the post-mortem examinations at both institutions are in charge of the Professor of Pathology, and afford ample material for study of this subject. Students are able to attend the practice of the Jessop Hospital for Diseases of Women and the Hospital for Sick Children, while special courses on fevers are given at the City Fever Hospital, and on mental diseases at the South Yorkshire Mental Hospital.

Appointments.—The following appointments are open to all students who have passed their examinations in anatomy and physiology: (1) casualty dresserships, (2) surgical dresserships, (3) medical clerkships, (4) pathological clerkships, (5) ophthalmic clerkships, (6) clerk to the skin department, etc. These appointments are made for three months, commencing on the first day of October, January, April, and July.

Scholarships.—Entrance Medical Scholarship, covering cost of tuition fees for a degree course in the Faculty of Medicine, open to both sexes. Six Edgar Allen Scholarships of £100 a year for three years may be held by students taking the degree course in medicine. Two Town Trustees Scholarships, each of the value of £50 a year, tenable for three years, for boys or girls who have been educated in a Sheffield secondary school for a period not less than two years immediately preceding the examination. Four Town Trustees Scholarships, value £50 a year, for boys or girls under 19 years of age educated in any school in Sheffield, secondary or otherwise. Town Trustees' Fellowship, value £75, tenable for one year. Mechanics' Institute Scholarship, value £50 (with remission of fees), tenable for one year, and renewable for a second year. The Frederick Clifford Scholarship, value about £50, tenable for two years, Kaye Scholarship, value £60, for proficiency in anatomy and physiology. Gold and bronze medals are also awarded for proficiency in various subjects.

Fees.—Students in the Faculty taking their complete medical course in the university pay an inclusive composition fee of £42 for each of the first five years and £28 for the sixth year. The composition fees for the dental courses are as follows: for B.D.S., first and third years, £80; second, fourth, and fifth years, £30; for L.D.S., first and second years, £80; third and fourth years, £30. The fees for special courses taken separately can be ascertained by inquiry of the Dean.

Welsh National School of Medicine

The next session opens on October 5. All classes are open to both men and women students. Particulars relating to the admission of students can be obtained on application to the Provost, or to the Secretary, Welsh National School of Medicine, the Parade, Cardiff. (See further details under University of Wales (p. 456.)

SCOTLAND

As will be gathered from the following paragraphs, the facilities for acquiring a medical education in Scotland are very ample, whether the student be proceeding to a university degree or to a diploma. To the descriptions of the different Scottish medical centres is in some cases added an account of hospitals which either play an official part in the education given to students as yet unqualified, or offer valuable opportunities for postgraduation work.

Aberdeen

The school is conducted by the Faculty of Medicine. This comprises twelve chairs, from which instruction is given in all the main branches of medical science—namely, biology, physics, chemistry, anatomy, physiology, materia medica, pathology, bacteriology, surgery, medicine, and midwifery. Courses of instruction in forensic medicine, public health and infectious diseases, tropical medicine, medical ethics, tuberculosis, and clinical methods are conducted by lecturers appointed by the University Court. Special opportunities for practical instruction are afforded in the laboratories and museums attached to the departments.

Clinical instruction is obtained in the Royal Infirmary, the Royal Mental Hospital, the Sick Children's Hospital, the City Fever Hospital, the General Dispensary, Maternity, and Vaccine Institution, and the Ophthalmic Institution. Courses of practical instruction are given in diseases of children at the Sick Children's Hospital; in fevers at the City Fever Hospital; in mental diseases at the Royal Mental Hospital; in diseases of the ear, nose, and throat at the Infirmary and Dispensary; in diseases of the eye at the Infirmary and Eye Institution; in venereal diseases and diseases of the skin at the Royal Infirmary.

The degrees granted in medicine are: Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.). A diploma in public health is conferred after examination on graduates in medicine of any university of the United Kingdom. The degree of Ph.D. is also granted in this faculty.

Fees.—An inclusive fee of 126 guineas is payable for instruction within the university, and the fee for the degrees of M.B., Ch.B. is 33 guineas. The total cost, including hospital fees, class and matriculation fees, and degree fees, is about £240.

Bursaries, scholarships, and fellowships, to the number of fifty, and of the annual value of £1,200, may be held by students of medicine in this university. The bursaries range in value from £10 to £50 per annum, and are tenable for periods from one to five years.

Edinburgh

There are two Schools of Medicine: the School of the University, and the School of Medicine of the Royal Colleges of Physicians and Surgeons of Edinburgh.

THE UNIVERSITY SCHOOL.—This school, in addition to other resources of the university, has the following means of affording practical instruction: Royal Botanic Garden, Herbarium, and Museum; zoological laboratory and museum of science and art; physical laboratory; chemical laboratories; dissecting room, bone room, and anatomical museum; physiological laboratory; medical jurisprudence laboratories; John Usher Institute of Public Health; materia medica museum and laboratory; post-mortem department of the Royal Infirmary and University Pathological and Bacteriological Laboratory; tutorial classes of practice of physic, of clinical medicine, and clinical surgery, surgery and midwifery; and the practice of certain other hospitals.

Fees.—The sessional fee for chemistry, anatomy lectures, physiology, pathology, materia medica, surgery, medicine, and midwifery is £6 6s. each. Physics, botany, zoology, forensic medicine, and public health, £5 5s. Practical zoology, practical anatomy (summer), morbid anatomy, practical materia medica, mental diseases, practical pathology, clinical midwifery, and medical entomology and parasitology, £4 4s. Experimental physiology, diseases of tropical climates, practical botany, histology, child life and health, operative surgery, clinical surgery (per term), and clinical medicine (per term), £3 3s. Practical anatomy (winter), £6 16s. 6d. Practical chemistry, £4 14s. 6d., chemical physiology, surgical pathology, and infectious diseases, £1 11s. 6d. Tuberculosis, diseases of the eye, diseases of the larynx, ear, and nose, diseases of the skin, and venereal diseases, £2 12s. 6d. Advanced bacteriology, £7 17s. 6d. Clinical gynaecology, regional anatomy, and applied anatomy, £2 2s.

Scholarships.—There are many funds for the assistance of students by means of bursaries, scholarships, exhibitions, and money awards from the beginning to the end of their undergraduate career. In addition, there are funds which help those who have taken a first degree in medicine and surgery to continue at work as research students. The value of these awards, and the conditions attaching to them, are so varied that those interested should consult the prospectus of the school itself.

THE SCHOOL OF MEDICINE OF THE ROYAL COLLEGES.—This school is composed of Lecturers licensed by the Royal College of Physicians and the Royal College of Surgeons and in most cases also recognized by the University of Edinburgh through their *licentia docendi*; for the sake of convenience they lecture in separate buildings near to the Royal Infirmary, but form a single body governed by a Board elected by the Royal Colleges of Physicians and Surgeons and by the Lecturers. This Board, with the assistance of the standing committees of the School, supervises the whole management and especially the maintenance of the efficiency and discipline of the school. The buildings at present utilized for the purposes of lecturing are the following: (1) Surgeons' Hall, Nicolson Street; (2) New School, Bristo Street; (3) Dental Hospital, Chambers Street. Clinical classes are held in the Royal Infirmary, Royal Maternity Hospital, and other institutions. The teaching is similar to that of the Scottish universities, and the students receive similar certificates at the close of each session. The courses on the special subjects are also conducted by teachers specially qualified in each branch. The fees payable for class and other instruction, and including the sums payable before admission to the examinations of the Conjoint Board for the Triple Qualification, amount to about £180. The Calendar, giving full information regarding classes and fees, can be obtained (price 1s. post free) on application to the Dean of the School, Surgeons' Hall, Edinburgh.

Glasgow

The whole course of study required for graduation (M.B., Ch.B.) at the University of Glasgow can be taken here. Besides ample provision for lectures there is practical and clinical work at the hospitals, and practical courses are conducted in the laboratories of the following departments: pathology, public health, pharmacology, physiology, surgery, anatomy, chemistry, zoology, physics, and botany; the Botanic Garden and the Hunterian Museum are also open to students. Well-equipped buildings have been provided for zoology, practical anatomy, and operative surgery, as well as for pathology. The classrooms and laboratories for the departments of botany, physics, physiology, pharmacology, materia medica, medical jurisprudence, and public health are also of recent erection, and are elaborately equipped. In addition to the regius chairs and the chair of pathology at the university, there are the chairs of medicine, surgery, obstetrics, and pathology at the Royal Infirmary; and a number of university lectureships in clinical medicine, clinical surgery, venereal diseases, laryngology, dermatology, otology, psychological medicine, tuberculosis, pathological biochemistry, and medical radiology have been founded there. Other chairs have been founded at the university in bacteriology, organic chemistry, physiological chemistry, applied physics, public health, paediatrics, and ophthalmology. There are also lectureships on the surgical and medical diseases of children and on medical radiology. The university, in short, has made great and successful efforts to extend and improve the accommodation of the medical departments, to strengthen the teaching staff, and to encourage postgraduation and research work. A diploma in public health is now also granted. Three very extensive general hospitals in the city afford exceptional opportunities for clinical instruction—namely, the Western

Infirmary (600 beds), near the university, to which the Regius Professors are attached; the Royal Infirmary (824 beds); and the Victoria Infirmary (380 beds); while the Royal Mental Hospital, Gartnavel (500 beds), the Royal Hospital for Sick Children (350 cots), the Royal Maternity and Women's Hospital (114 beds), the Glasgow Eye Infirmary (100 beds), the Ophthalmic Institution (35 beds), the fever hospitals at Belvidere (680 beds), Ruchill (540 beds), and Mearnskirk, and other institutions afford facilities for the practical study of special branches. The large general hospitals of the town council are now also available for clinical instruction in medicine and surgery. Information regarding postgraduate study will be found at page 487.

Bursaries.—Bursaries confined to the Medical Faculty amount in annual value to about £1,250, while bursaries in any faculty, amounting to about the same annual sum, may be held by students of medicine, a number of both sets being open to women. Postgraduate scholarships approximate in value to £3,500 per annum.

The following bursaries are open for competition to students entering on their first session of attendance in the Faculty of Medicine: Davidson Bursary, annual value £40, tenable for four years, for students who propose before entering the Faculty of Medicine to take the degree of B.Sc. in pure science, including in their curricula anatomy and physiology. Highland Society (Glasgow) Bursaries, annual value £25 each, tenable for five years, for students of Highland descent, open to women; two bursaries vacant each year. Logan Bursary, annual value £25, tenable for four years, open to women. Robina Eckford MacBrayne Scholarship, annual value £50, tenable for three years. Marshall Bursary, annual value £24, tenable for four years. Merchants' House Bursary, annual value £35, tenable for four years, open to women. John Oliphant Bursary, annual value £35, tenable for six years. James A. Paterson Bursaries, three each year of the annual value of £30, £25, and £15 respectively, each tenable for four years; students entering their second session are also eligible; open to women; examination in mathematics and natural philosophy.

Candidates for the bursaries mentioned above must take the university general bursary competition, which is held each year in the month of June.

In addition, the following bursaries, scholarships, and prizes are open to students prosecuting their studies in the Faculty of Medicine: Arbroath Bursary, annual value £35, tenable for three years, is awarded by the Senate, on the recommendation of the Faculty of Medicine, to the student who is of the highest merit among the candidates as shown by their class records and their performances in the First and Second Professional Examinations. Arthur Bursary, annual value £20, tenable for three years, awarded to the *woman* candidate who takes the highest place at the First Professional Examination. Bell Bursaries, annual value £50 each, tenable for the duration of the course, for students who have gone through the curriculum in arts; tenable also in theology or law. Brisbane Bursary, annual value £50, tenable for four years; candidates must be under 22 years of age, and must have taken the degree of M.A. John Buchanan Bursary, £80 for two years, awarded at beginning of third year on the results of the First Professional Examination, plus a modern language taken in the general bursary competition. William Gardiner Bursary, annual value £18, tenable for two years, awarded on results of the First and Second Professional Examinations in the subjects of physiology, chemistry, and physics. Dr. Thomas Gibson Bursary, annual value £50, tenable for four years; open to medical students entering on their second winter who are preparing for service as medical missionaries. Johnston Bursaries, annual value £25 each, tenable for three years, for eminence in the work and examinations of the first and second years of the curriculum. Lorimer Bursaries (six), value £20 each, tenable for one year, are awarded to the best students in each of the following classes: botany, zoology, physics, chemistry, anatomy, physiology. Macarthur Bursary, of the annual value of £20 and tenable for two years, for students entering on their fourth session of medical study. Macfarlane Bursary, annual value £40, tenable for three years, for students who have attended the first session of their professional study in the university; examination in elementary anatomy, elementary chemistry, and botany. Mackintosh Bursary, value £31, tenable for one year, open to medical students of either sex who have attended one of the courses of lectures on insanity in the university; examination in that subject. John Monteith Bursary, annual value £21, tenable for two years, is awarded annually to the student who gains the highest number of marks in the subjects of anatomy and physiology at the professional examinations held during the previous year. Rainy Bursary, annual value £50, tenable for two years, for students entering on their third session of medical study; awarded to the candidate whose aggregate of marks in the subjects of anatomy and physiology of the Second Professional Examination, and in chemistry, botany, and zoology of the First Professional Examination, is the highest. A. and B. Stewart Postgraduate Bursaries, annual value £50 each, tenable for the duration of the course, for students who have gone through the arts curriculum. Walton Bursary, annual value £40, tenable for four years; the Earl of Sandwich has the right of appointing to the bursary one of two students nominated by the Senate. Weir Bursary, value £25, tenable for one year, awarded on the results of the Second and Third Professional Examinations. Barbour Scholarship in anatomy or physiology, annual value £250, tenable for two years. Joseph Coats Memorial Scholarship, value £85, tenable for one year, for research in pathology, may be held concurrently with the Perman Memorial Scholarship (q.v.). Faulds Fellowship, annual value £250, tenable for three years, for medical research. Foulis Memorial Scholarship in pathology, value £50. Hall Tutorial Fellowships approximately £250 for one year. Four McCunn Medical Research Scholarships, value £200 each, tenable for one year. Perman Memorial Scholarship, value £85, tenable for one year, for research in pathology, may be held concurrently with the Joseph Coats Memorial Scholarship (q.v.). Henderson Research Scholarship, of about £250 per annum, for research in mental diseases. Hutchison Research Scholarship, of the annual value of £110, for research in certain subjects in the medical curriculum. Reid Stewart Postgraduate Bursary, £200 for one year, for special study and research; renewable. Mary Margaret Isabel Ure Scholarship, of the annual value of about £300, for research in cancer or tuberculosis or other branch of study approved by the Faculty of Medicine. John Reid Prize, of £25, for the best original research conducted in one or more of the hospitals or scientific laboratories in Glasgow, bearing on any department of medical science. History of Medicine Prize, of about £50, for the best essay on some subject in the history of the science or practice of medicine, other than a subject of recent development in some limited branch thereof. Harry Stewart Hutchison Prize, value £50, for original research work relating to children. The Junior Arnott Prize of about £15; the Senior Arnott Prize of £25. Three Bellahouston Gold Medals. The Brunton Memorial Prize of about £20. The Macewen Medal in surgery. The Captain H. S. Ranken V.C. Memorial Prize of £5. The Straits Settlements Gold Medal. The West of Scotland R.A.M.C. Memorial Prize of about £15. Asher Asher Memorial Gold Medal, awarded annually in connexion with the class on diseases of the throat and nose. Macfarlane Prizes of £10 each, in each of the classes of medicine. Macleod Medal, awarded annually to the most distinguished student, man or woman, in the class of systematic surgery taught by the Regius Professor. Struthers Gold Medal, awarded in anatomy for the best original research or for the best special dissection or preparation or series of dissections or preparations.

The Carnegie Trust for the Universities of Scotland is empowered to pay the whole or part of the university ordinary class fees of students of Scottish birth or extraction, under conditions given in the University Calendar. Scholarships and Fellowships are offered by the Carnegie Trust in science and medicine for postgraduation study.

Fees.—The matriculation fee for each year is £2 12s. 6d. In most cases the fee for each university class is £6 6s., but in some cases it is £4 4s. For hospital attendance at the Western Infirmary students pay £12 12s. for a perpetual ticket, or £1 11s. 6d. for a single term ticket, with an additional fee of £5 5s. for each winter and £2 12s. 6d. per term for each clinical course. The fees are the same at the Royal Infirmary. The university fees for the four professional examinations total £34 13s. For the whole curriculum the fees for matriculation, class attendance, hospital attendance, and professional examinations amount to about £250.

For further information apply to the Registrar, Glasgow University.

ST. MUNGO'S COLLEGE.—This is the Medical School of the Royal Infirmary, which is the largest general hospital in Glasgow. The Infirmary is situated in Cathedral Square, Castle Street, and has car communication with

every part of the city. St. Mungo's College is in the Infirmary grounds, and affords full courses in all the subjects of the medical curriculum, and in all the medical subjects of the dental curriculum.

The Infirmary has (including the ophthalmic department) 794 beds—554 for surgical and 240 for medical cases. There are special beds and wards for diseases of women, of the throat, nose, and ear, burns, and septic cases. In the out-patient department in 1936 119,914 patients were treated. In addition to the large medical and surgical departments, there are departments for special diseases—namely, diseases of women, of the throat and nose, of the ear, of the eye, of the skin, and of the teeth. There is also a fully equipped electrical pavilion, with the latest and most improved apparatus for diagnosis and treatment.

Appointments.—Five house-physicians and eleven house-surgeons, who must be fully qualified, are appointed every six months, and board in the hospital free of charge. Clerks and dressers are appointed by the physicians and surgeons. As many cases of acute diseases and accidents of a varied character are received, these appointments are very valuable.

Fees.—The average class fee is £3 3s. for summer classes and £4 4s. for winter classes. The fees for all the lectures, practical classes, and hospital attendance necessary for candidates for the diplomas of the English or Scottish Colleges of Physicians and Surgeons amount to about £120. The classes are open to male and female students.

A syllabus of classes can be obtained on application to the Secretary to the Medical Faculty, St. Mungo's College, 86, Castle Street.

THE ANDERSON COLLEGE OF MEDICINE.—This school provides education in the subjects of the curriculum for both medical and dental students. The school buildings are situated in Dumbarton Road, immediately to the west of the University and Western Infirmary. The hospital practice and clinical lectures are provided in the Western or Royal Infirmary; pathology in the Western or Royal Infirmary; vaccination and dispensary practice in the Western or Royal Infirmary Dispensary. These classes are recognized by all the licensing corporations in the United Kingdom, also by the Universities of London, Glasgow, and Edinburgh (the latter two under certain conditions stated in the School Calendar).

Fees.—The fees for the lectures and practical work required by ordinary students range between 2 and 6 guineas a class. The Carnegie Trust pays the fees of students at Anderson College on conditions regarding which particulars may be obtained from the Secretary, Carnegie Trust Offices, Edinburgh.

A Calendar will be sent on receipt of a postcard by the Secretary to the Medical Faculty, the Anderson College of Medicine, Glasgow, W.1, who will forward any further information which may be desired.

The Royal Samaritan Hospital for Women, Glasgow, has 190 beds, of which 30 are for paying patients of limited means, and offers excellent facilities for clinical instruction in the diseases peculiar to women. A new radiological department, with the most modern apparatus for treatment, was recently opened. Lectures and clinical demonstrations are given by members of the surgical staff. There is a complete course each university term for university students and one course in the summer term for college students. A postgraduate course is held during the summer months and a series of demonstrations for general practitioners is carried out in the winter. The hospital is represented on the Board of the Glasgow Postgraduate Medical Association formed for co-ordinating postgraduate medical teaching. The Royal Samaritan lectureship in gynaecology is a university lectureship associated with the hospital.

St. Andrews and Dundee

The medical departments in these two teaching centres cater specially for students proceeding to the degrees of the University of St. Andrews, but admit other students as well. In the former city the United College provides education in all subjects for the first two years. In Dundee, University College provides for the needs of students from the beginning to the end of the five years' curriculum. Its buildings are modern, and contain fully equipped laboratories. The clinical work of the school is facilitated by various institutions. The class fees are from £6 6s. to £5 12s. 6d. for systematic classes, and from £4 14s. 6d. to £4 4s. for practical classes. The hospital ticket is £1 8s. for three months, £4 4s. a year, or perpetual, £13 6s. 8d. in one sum. The inclusive or composition fee for the curriculum is £182. In connexion with both institutions there are bursaries and scholarships of considerable value, which are awarded after competitive examination. Information as to these can be obtained from the Secretary of the University of St. Andrews. Information regarding the clinical facilities may be obtained from the Dean of the Medical Faculty, Medical School, Dundee.

CLINICAL WORK

Good opportunities for clinical work are afforded by the Dundee Royal Infirmary and Maryfield Hospital, the instruction given thereat being recognized for purposes of graduation by all the Scottish universities, the University of Cambridge, the University of London, the National University of Ireland, and by the Royal Colleges of England and Scotland.

IRELAND

There is a choice of six schools for those pursuing their medical studies in Ireland. For clinical instruction the choice is equally wide and varied, though the hospitals themselves are comparatively small. Some account of the schools follows.

Dublin

SCHOOL OF PHYSIC

This school is in Trinity College, Dublin, and is carried on under the joint auspices of the University of Dublin and of the Royal College of Physicians of Ireland, the King's professors of institutes of medicine (physiology), practice of medicine, materia medica, and midwifery being appointed by the latter. Clinical instruction is given at Sir Patrick Dun's Hospital, and some twelve other metropolitan hospitals and asylums are recognized by the Board of Trinity College. The courses of instruction are open to all medical students, whether they belong to the university or not.

THE SCHOOLS OF SURGERY

These are schools carried on in Dublin under the supervision and control of the Council of the Royal College of Surgeons. They are formed of the college's own school, combined with two famous old medical schools—Carmichael and Ledwich; they are attached to the college by charter. The buildings contain spacious dissecting rooms, special pathological, bacteriological, and chemical laboratories. Advantage can be taken of the lectures and instruction afforded by students otherwise unconnected with the college.

Prizes.—Among the prizes annually awarded are: The Barker Anatomical Prize (£26 5s.); the Carmichael Scholarship (£15); the Mayne Scholarship (£8); the Gold Medal in surgery; the Stoney Memorial Gold Medal in anatomy; the H. Macnaughton Jones Gold Medal for midwifery and gynaecology; the Captain Massey Miles Memorial Prize; class prizes, accompanied by silver medals, will also be given in each subject.

A prospectus can be obtained post free on application to the Registrar, Royal College of Surgeons, Dublin.

UNIVERSITY COLLEGE, DUBLIN

This is one of the constituent colleges of the National University of Ireland. The arrangements for the teaching of medical students from beginning to end of the curriculum are adequate. Applications for information may be addressed to the Secretary and Bursar, University College, Dublin.

CLINICAL TEACHING IN DUBLIN

Two other important obstetric and gynaecological hospitals in Dublin are the Coombe Lying-in Hospital and the National Maternity Hospital. During the year 1934 the number of cases dealt with in the Coombe Lying-in Hospital were as follows: intern maternity department, total admissions 1,504, total deliveries in hospital 1,254; extern maternity, 1,491 deliveries; gynaecological department, admissions 517. Attendance at pre-natal clinic, baby, and general dispensaries 12,000 cases yearly. The practice of these hospitals is attended by large numbers of students, postgraduates, and nurses, who come from all parts of the world.

There are numerous well-arranged hospitals in and around the city, and almost all of these are recognized for teaching purposes by the Conjoint Board of Ireland, the University of Dublin, the National University of Ireland, and by like bodies elsewhere in the British Isles. Among them are the Mater Misericordiae Hospital, with 345 beds; Dr. Steevens' Hospital at Kingsbridge, with 150; Meath Hospital and County Dublin Infirmary, with 160; Mercer's Hospital with 120; the Royal City of Dublin Hospital, with 124; the Adelaide Hospital, with 160; the Royal Victoria Eye and Ear Hospital, with 100; Sir Patrick Dun's Hospital, which has a direct connexion with the School of Physic, with 129 beds; and the combined institutions formed by the Hardwicke Fever Hospital, the Richmond Surgical Hospital, and the Whitworth Medical Hospital, with an aggregate of 330 beds. Other hospitals are: the Children's Hospital, Temple Street, with 125 beds; the National Children's Hospital, with 53 beds; St. Ulten's Infants' Hospital, with 52 beds; St. Mary's Orthopaedic Hospital at Cappagh, with 236 beds; and St. Anne's Skin and Cancer Hospital, with 60 beds.

As for the famous Dublin medical institution known as the Rotunda Hospital, this practically consists of two distinct hospitals, and it is believed to be the largest combined maternity and gynaecological hospital in the British Isles. There are pre-natal and paediatric departments, as well as a thoroughly equipped pathological laboratory, biochemical laboratory, and x-ray apparatus. It possesses residential quarters for students, accommodating over fifty, and, taken as a whole, offers exceptional opportunities for study, both to ordinary students and to medical graduates of any nationality. During the year ending October 31, 1934, there were 3,173 maternity admissions. Including patients treated in their homes, the Rotunda dealt with 5,372 cases during the year, of which 4,688 were delivered. In the gynaecological department there were 687 admissions, of which 553 were operated upon. The attendances at the out-patient department totalled 20,736. Extensive alterations and additions to the hospital are being undertaken.

The National Maternity Hospital is now housed in new buildings. This hospital is of the most modern and up-to-date type, both in lay-out and in equipment. It contains many novel and original features, and much of the equipment and furniture has been specially designed. It is run entirely on electricity, no other fuel being used. At present it consists of accommodation for some eighty-five patients, together with all central services and excellent accommodation for students and staff. This new building was opened for the admission of patients on January 1, 1935. The old hospital has been abandoned, and is being demolished to make room for the building of the final wing of the new hospital to accommodate sixty-five additional beds. During the year 1934 the hospital dealt with 2,367 maternity cases, of which 2,019 were delivered. In the gynaecological department 351 patients were admitted. The attendances at the out-patient department were 7,842. Clinical instruction is given daily.

Belfast

The Medical School is part of the Faculty of Medicine of Queen's University, Belfast, and provides a complete medical curriculum for all purposes. The laboratories in the departments of bacteriology, biochemistry, biology, chemistry, physiology, pathology, public health, anatomy, physics, and materia medica are all excellent. and there is a students' union which gives students the advantages of dining rooms, reading rooms, a library, and various recreation rooms. Women are eligible as students. Clinical instruction is given at the Royal Victoria Hospital, which was rebuilt a few years ago and has 500 beds, of which 64 are in the Royal Maternity Hospital, and the Mater Infirmorum Hospital, which has 150 beds. Other hospitals open to the students of the university are: the Ulster Hospital for Women and Children; the Hospital for Sick Children; the Ophthalmic Hospital; the Benn Ulster Eye, Ear and Throat Hospital; the Union Infirmary and Fever Hospital; the Fever Hospital, Purdysburn; the District Lunatic Asylum; the Samaritan Hospital; the Forster Green Hospital for Diseases of the Chest; and the Belfast Hospital for Skin Diseases.

Scholarships.—(1) Eight, of the value of £40 each, are assigned as Entrance Scholarships in the Faculties of Arts, Science, and Medicine, tenable for one year; (2) fourteen Professional Scholarships, value from £15 to £40 each; (3) one Hutchinson Stewart Scholarship, £12, in mental diseases; (4) one Mackay Wilson Travelling Scholarship, £100, awarded triennially (next award, 1939); (5) Isabella Tod Memorial Scholarship, tenable for three years, awarded triennially to a woman student; (6) Magrath Clinical Scholarship, awarded annually, value about £112; (7) two Musgrave Studentships of £200 in physiology and pathology. There is also a post-graduate research fund, open to all graduates of not more than three years' standing. Gold medals are awarded at the M.D. examination.

Fees.—The cost of the curriculum intended for students proceeding to the degrees of the Queen's University of Belfast is approximately £230. This includes examination fees and a perpetual ticket for attendance at the Royal Victoria Hospital or the Mater Infirmorum Hospital, and fees for the special hospitals. The course for the Conjoint Board costs about the same amount.

The Regulations of the Medical Faculty, containing full information, can be obtained on application to the Bursar, Queen's University, Belfast, price 4d.

University College, Cork

This institution, formerly known as Queen's College, Cork, is one of the constituent colleges of the National University. It holds examinations for all the faculties of that university, in addition to continuing the work which it has hitherto performed—namely, that of providing education adapted to the needs of medical students at all stages of their career. Its first aim is to fit students for the degrees of the National University, but students proceeding for the examinations of the Conjoint Board of England, Scotland, or Ireland, the Society of Apothecaries of London or the Apothecaries' Hall of Ireland, or London University, can arrange the courses of lectures which they attend, and the order in which they attend them, to meet the requirements of those bodies. Certificates of attendance at the college courses are also accepted by the University of Cambridge. Clinical instruction is given at the North and South Infirmaries (each 100 beds) and at the Cork Union Hospital (1,200 beds). Students can also attend the Mercy Hospital (130 beds), the County and City of Cork Lying-in Hospital, the Hospital for Diseases of Women and Children, the Fever Hospital, the Ophthalmic and Aural Hospital, and the Eglinton Lunatic Asylum. The session extends from October to June.

Scholarships.—About £2,500 is available annually for scholarships in the college. Particulars as to each of them can be obtained on application to the Registrar.

Fees.—The fees for the lectures and hospital attendances required by the National University of Ireland course, including examination fees, come to about £200.

Further information can be found in the Calendar, or obtained on application to the Registrar.

University College, Galway

This institution is one of the constituent colleges of the National University of Ireland, and includes Faculties of Art, Science, Law, Celtic, Engineering, Commerce, and Medicine. The college buildings are well lighted and well ventilated, and contain dissecting rooms, an anatomical theatre, and laboratories for the study of physiology, chemistry, physics, and other departments of medical

science. For pathology and chemistry new laboratories are now provided. It has good grounds surrounding it, and there are many arrangements, such as a library, a college union, and an athletic union, for the benefit of those belonging to the Medical Faculty, as well as for students in other departments of the college. The clinical teaching, which is recognized as qualifying not only for the degrees of the National University but for those of the London University and the diplomas of the various colleges in the three kingdoms, is carried on at the Galway Central Hospital and the Galway Tuberculosis Hospital. The Galway Central Hospital is a general hospital, and at the two hospitals students have ample opportunities of studying zymotic and chronic diseases. The Central Hospital has a special ward for diseases of children. Each year the governing body offers about £2,500, and the County Councils of Connaught offer about £3,500 in scholarships. These scholarships are tenable in any faculty. Additional information regarding these scholarships can be obtained on application to the Registrar, and to the Secretaries of the Connaught County Councils.

CLINICAL HOSPITALS IN ENGLAND

Many hospitals in Great Britain and Ireland, though not connected with any medical school, open their doors either to those who have yet to be qualified, to those who are doing postgraduation work, or to both. The facilities they offer for gaining practical clinical experience are very great, and should not be overlooked. Their honorary staffs commonly make a point of giving such instruction as opportunity offers, and at those situated in the larger towns there are often appointments as clinical assistants to be obtained. In addition, they all have to offer, at shorter or longer intervals, appointments for resident medical officers, house-physicians, and house-surgeons. These are usually paid offices, which may be held for periods varying from six months to a year, or even longer. Some of those situated in the great medical centres in the provinces, and in Scotland and Ireland, have already been mentioned in speaking of the medical schools in these localities; but it should be added that there are many other provincial hospitals where admirable work is done, and at which much valuable experience can be gained by both senior and junior students, and by those already qualified. Cases in point are the Royal Infirmary, Bradford; the Royal Sussex County Hospital, Brighton; the Royal United Hospital, Bath; the Worcester General Infirmary; the Kent and Canterbury Hospital; the Derbyshire Royal Infirmary; South Devon and East Cornwall Hospital, Plymouth; the Royal Albert Hospital and Eye Hospital, Devonport; the Royal Devon and Exeter Hospital; the West of England Eye Infirmary, Exeter; the Gloucestershire Royal Infirmary and Eye Institution; the Royal Infirmary, Leicester; the County Hospital, Lincoln; the General Hospital, Northampton; the Norfolk and Norwich Hospital; the General Hospital, Nottingham; the Royal Portsmouth Hospital; the Royal Berks Hospital, Reading; the Royal South Hants and Southampton Hospital; the Staffordshire General Infirmary, Stafford; the North Staffordshire Royal Infirmary at Stoke-on-Trent; the Royal Hants County Hospital, Winchester; the Wolverhampton and Staffordshire General Hospital; the County Hospital, York; and the Coventry and Warwickshire Hospital.

London Clinical Hospitals

As for the hospitals in the metropolis, so many of these take a share in the giving of clinical instruction that it is worth while to classify them.

Children's Hospitals.—There are at least seven of these, the leader among them being the Hospital for Sick Children, Great Ormond Street, which has 268 beds. There are also the Princess Elizabeth of York Hospital for Children, Shadwell, with 136; the Queen's Hospital for Children, Bethnal Green, with 134; the Victoria Hospital for Children, Chelsea, with 130; the Belgrave Hospital for Children, which has a considerable out-patient department and in-patient accommodation for 74 children; the Paddington Green Children's Hospital; and the Evelina Hospital for Sick Children, Southwark Bridge Road, with 76 beds. The largest and the oldest of the hospitals for both women and children is the Royal Waterloo Hospital for Children and Women, Waterloo Road, S.E.1.

Hospitals for Women.—Queen Charlotte's Maternity Hospital, Marylebone Road, with 100 beds and a residential college for medical students and practitioners, specializes in the teaching of midwifery. The first section of the new Queen Charlotte's Hospital in Goldhawk Road, Hammersmith, an isolation block of 30 beds for cases of puerperal fever and puerperal pyrexia, was opened in July, 1930. The Bernhard Baron Research Laboratories, immediately adjoining the isolation block, were opened towards the end of 1930, and are fully equipped and staffed. The City of London Maternity Hospital Midwifery Training School, City Road, E.C.1, admitted 1,724 mothers last year, and 2,701 were attended at its ante-natal clinics. Residential accommodation is provided for two male students, who are afforded excellent facilities for observing operative midwifery and obstetrical complications. Twenty deliveries are guaranteed to students entering for the four-weeks course to encourage them to take the longer period. Certificates acceptable by the examining bodies are issued. Postgraduates are admitted to the ante-natal clinics by arrangement, and week-end postgraduate courses are arranged from time to time. The Samaritan Hospital for Women, Marylebone Road, admits qualified practitioners as clinical assistants to both the in-patient and the out-patient departments; demonstrations are given daily in both departments, the fees—payable in advance—being £3 3s. for three months; full particulars may be obtained from the secretary. In addition may be mentioned the Hospital for Women, Soho Square, whose teaching is confined to postgraduates in limited numbers; the Chelsea Hospital for Women, Arthur Street, Chelsea; and the Elizabeth Garrett Anderson Hospital for Women in Euston Road, the latter being in the nature of a general hospital so far as concerns the class of case treated.

Eye Hospitals.—The largest of these is the Royal London Ophthalmic Hospital (Moorfields), City Road, E.C.1, 200 beds; 4,203 in-patients, 54,941 out-patients in 1936. At this hospital two complete courses of instruction are given during the year—October to February, and March to July—comprising the following subjects: (1) anatomy (including histology and embryology), (2) physiology, (3) optics (including physiological optics), (4) refraction classes, (5) methods of examination and use of the ophthalmoscope, (6) pathology and bacteriology, (7) ophthalmic medicine and surgery, (8) ophthalmoscopic conditions, (9) operative surgery, (10) practical pathology, (11) practical bacteriology, (12) radiology, (13) physiotherapy (including ultra-violet light, diathermy, and ionization), (14) slit-lamp microscopy. Registered medical practitioners and medical students are eligible, under certain conditions, for the posts of chief clinical assistant, clinical assistant, and junior assistant. There are also a number of salaried posts, an annual Clinical Research Scholarship of £50, and a biennial Gifford Edmunds Prize of £100. Clinical work begins each morning at 9 and operations at 10 o'clock. The course of instruction is specially adapted to meet the requirements of those reading for the D.O.M.S. and similar diplomas and degrees in ophthalmology. The Out-patient Department, Medical School, and Laboratories have been rebuilt and enlarged. Further particulars may be obtained from the Dean of the Medical School.

Other eye hospitals are the Royal Westminster Ophthalmic Hospital, now rebuilt on a new site in Broad Street, High Holborn, and containing 84 beds; the Royal Eye Hospital, Southwark; and the Central London Ophthalmic Hospital, Judd Street, W.C.1, each with about 40 beds; and the Western Ophthalmic Hospital with 35 beds, including ten single-bed wards. At the Royal Eye Hospital special classes are held in May and October to meet the requirements of students preparing for the D.O.M.S. and similar examinations. Clinical classes in medical ophthalmology are held for candidates for the M.R.C.P. examinations. A course suitable for general practitioners is held in April under the auspices of the Fellowship of Medicine. The pathological and bacteriological departments are available to ophthalmic surgeons and institutions desiring reports on specimens, cases of interest being dealt with without charge. A research scholarship in ophthalmology to the value of 100 guineas per annum is awarded yearly.

Fever Hospitals.—The London County Council has under its control a number of institutions in and around London for the treatment of the more serious zymotic disorders: it makes special arrangements for the instruction of students in this subject, and grants certificates at the end of the courses. The fees for medical undergraduate and post-graduate instruction at the L.C.C. hospitals for infectious diseases, including small-pox, are as follows: Course in diagnosis and treatment of fevers, three guineas for two months' course. Course in clinical practice and hospital administration (for candidates for the D.P.H.), three and a half guineas for 24 demonstrations and four guineas for thirty demonstrations. Course in diagnosis and treatment of small-pox (in cases in which a fee is payable), one guinea for three demonstrations. Detailed information should be sought from the Medical Officer of Health, Special Hospitals Division, London County Council, County Hall, S.E.1.

Chest Hospitals.—The largest of these is the Brompton Hospital for Consumption, which has 333 beds and a large sanatorium at Frimley with 150 beds. There is also the City of London Hospital for Diseases of the Chest, Victoria Park, with 185 beds, and the Royal Hospital for Diseases of the Chest, City Road, with 85 beds, now amalgamated with the Royal Northern Hospital, Holloway Road.

Nose, Throat, and Ear Hospitals.—The institutions which confine their work to disorders of the throat, nose, and ear all make special arrangements for the benefit of senior and postgraduate students. They are the Metropolitan Ear, Nose, and Throat Hospital, Fitzroy Square; the Royal Ear Hospital, Huntley Street, W.C.1 (now the Ear, Nose, and Throat Department of University College Hospital); the Central London Throat, Nose and Ear Hospital, Gray's Inn Road; and the Golden Square Throat, Nose and Ear Hospital, near Piccadilly Circus, W.1—the last, which possesses 101 beds, being the largest of the four institutions.

Miscellaneous Special Hospitals.—Among these are the Bethlem Royal Hospital, recently transferred from Kennington to Monks Orchard, Eden Park, Beckenham, Kent, which (like the Maudsley Hospital) confines its work to the treatment of mental diseases, and includes a department for nervous and early mental disorders; the Royal National Orthopaedic Hospital, Great Portland Street; St. Peter's Hospital for Stone and Urinary Diseases, Henrietta Street, Covent Garden; St. Mark's Hospital, City Road, which devotes itself to the treatment of diseases of the rectum, including cancer and fistula; St. Paul's Hospital, Endell Street, Holborn, W.C.2, where continuous postgraduate work in genito-urinary disease is carried on, and two regular postgraduate courses held each year; the National Hospital for Diseases of the Heart in Westmoreland Street, W.1; St. John's Hospital for Diseases of the Skin in Leicester Square: the Hospital for Diseases of the Skin, 71, Blackfriars Road, S.E.1; the National Hospital, Queen Square, W.C.1, an institution possessing 200 beds for neurological cases and a world-wide reputation; and the West End Hospital for Nervous Diseases, 73, Welbeck Street, W.1.

Detailed information as to the teaching arrangements of all these institutions may be obtained on application to their secretaries.

Women in Medicine

The regulations of the General Medical Council and of the various universities and colleges set out in previous sections apply to women as to men.

Examinations

Women are admitted to all the medical examinations of the following qualifying bodies: all the universities of Great Britain and Ireland; the Royal College of Physicians of London; the Royal College of Surgeons of England; the Society of Apothecaries of London; and the Conjoint Boards of the Colleges in Scotland and in Ireland. In addition, women are eligible for election as Fellows of the Royal College of Physicians of London, the Royal College of Physicians of Edinburgh, and the British College of Obstetricians and Gynaecologists.

Medical Education

In this country at the present time co-education is the general rule. Most of the schools of the London hospitals have, however, so far shown themselves more conservative in this respect than the rest of the country.

In England the colleges connected with the universities of Birmingham, Bristol, Cardiff, Durham, Leeds, Liverpool, Manchester, Newcastle, and Sheffield admit women students as well as men, whilst in Scotland the universities of Aberdeen, St. Andrews, Edinburgh, and Glasgow also admit women. In Ireland all universities and colleges are open to them.

In London the only schools open to medical women students are the London School of Medicine for Women and, to a modified extent, University College Hospital and King's College Hospital. It is felt that such a state of affairs can only be temporary, and hopes are entertained that in the near future the principle of co-education will prevail in the capital.

At the present time it will be seen that the only co-education hospitals in London are University College and King's College. The number of women entrants is restricted, but they are given excellent opportunities whilst students, and also, in fair proportion, are given opportunities of postgraduate experience as residents, house-surgeons, house-physicians, and obstetrical assistants.

Number of Women Students

Returns made to the University Grants Committee show that the total number of full-time women medical and dental students attending university institutions in England, Scotland, and Wales during recent years were:

	1925-6	1927-8	1929-30	1931-2	1933-4	1935-6
England	1,059	862	842	910	1,046	1,185
Wales	30	30	19	40	54	62
Scotland	313	254	275	322	425	500
Total	1,402	1,146	1,136	1,272	1,525	1,747

The corresponding total number of full-time male students of medicine, including dentistry, was 11,176 in 1935–6.

The London (Royal Free Hospital) School of Medicine for Women

The London (Royal Free Hospital) School was started for the training of women in medicine in the days before there were any co-education facilities for them, and it still remains by far the largest school for women. In addition to the clinical work at the Royal Free Hospital, which at present has upwards of 330 beds, arrangements are made for students of the school to obtain clinical instruction at the National Hospital for Nervous Diseases, Queen Square; the Royal London Ophthalmic Hospital, Moorfields; the Great Ormond Street Hospital for Children; the Elizabeth Garrett Anderson Hospital; the South London Hospital for Women; the Cancer Hospital; the Central London Ophthalmic Hospital; and certain hospitals administered by the L.C.C. Its importance for women in medicine can hardly be overestimated, not merely because it was the pioneer which made the way possible, but also because it is still the only general hospital in Britain which offers all its postgraduate appointments, higher and lower, to open competition by women as well as men, thus giving unique opportunity of gaining experience. Not only are all the resident appointments at the Royal Free Hospital, of which there are twenty-seven yearly, eligible for women, but, in addition, higher posts may be obtained in all the various branches of a general hospital, from those of registrar and anaesthetist to those of visiting physician or surgeon and those in charge of special departments. There is a special unit in gynaecology under a woman professor, and entirely staffed by medical women. This policy has so far not been fully adopted in its entirety by any other hospital. It may be of interest to note in this connexion that the Royal Free Hospital has many women on its

general committee and weekly board of management, and that the chairman of the latter is, at present, a woman.

Openings for Medical Women

There are at the present time the names of over six thousand medical women on the *Medical Register*. There is an increasing demand by the public for the services of women doctors, and the profession of medicine with its many and varied branches offers ample opportunity for a useful career. Statistics show that the proportion of those who make good is as high as, if not somewhat higher than, that of their men colleagues.

Openings at Home

Since the number of men and women qualifying has reached normal standards, medical women find no difficulty in obtaining house appointments in the recognized teaching hospitals and in non-teaching hospitals, hospitals for women and children, sanatoria, etc. The reorganization of hospitals under local authorities has resulted in the creation of a number of new resident appointments, senior and junior, intended to be held by medical women.

General Practice.—There are good openings as assistants or, better still, as assistants with a view to admission as partners in general practice. Medical women also do very well when starting in new districts; and there is considerable scope for them in midwifery work.

Specialist and Consulting Practice.—The number of women doing specialist and consultative practice grows rapidly. There is no branch of medicine in which it is not possible for a patient to consult a medical woman. Women so specializing equip themselves by obtaining the highest essential qualifications, and it is hoped that the time is not far distant when many more women will hold positions on the honorary staffs of all hospitals. Already medical women are on the honorary staff of the Royal Free Hospital, London, and of general hospitals in a number of provincial cities. In London, Edinburgh, Glasgow, Manchester, Bristol, and Brighton there are hospitals staffed entirely by medical women, doing very fine work and meeting a real need, the latest to be opened being the Marie Curie Hospital in London for the treatment of cancer by radium. Research work also provides interesting openings, as, for example, in dealing with the special problems concerning cancer, nutrition, puerperal morbidity and mortality, statistical work, etc., and for some of these research scholarships and grants are available.

Teaching Posts.—Women hold professorships and lectureships at various universities.

Industrial Medicine.—In this branch there is much interesting work available, and it is undergoing considerable development at the present time. Several women already hold such posts.

Administrative Work.—A certain number of these important posts are admirably filled by medical women. At the Ministry of Health the department for maternity and child welfare is staffed by medical women. Medical women also hold administrative posts under the Home Office, the Board of Education, the Boards of Control of both England and Scotland, the Post Office, etc.

The Public Health Service.—This service provides numerous openings for medical women. It has many departments, and its rapid growth in recent years has provided much interesting work in preventive medicine. Senior departmental posts are frequently held by medical women, and several occupy posts as medical officers of health. For maternity and child welfare work women have been found to be peculiarly suited; but, by a curious economic limitation, married women, who would appear to be the most suitable of all, have been, by many public authorities, excluded from service. A change of attitude, however, appears now to be taking place, as was evidenced by the decision of the London County Council to withdraw its ban against the employment of married medical women in its Public Health Service.

Medical Inspection, etc.—Under the Board of Education there are women serving as medical advisers and school medical inspectors. The London County Council and other important councils in the country have medical women on their permanent medical staffs, in both the senior and the junior grades. The London County Council has two of its senior medical women appointed to serve as district medical inspectors. In addition, they have a large number of women medical inspectors of school children, and also women are serving as experts in the departments dealing with mental deficiency, tuberculosis, and venereal disease. Some medical women also serve as examiners of the candidates entering the public services, as, for example, the civil service. The services of medical women are extensively enlisted by public authorities in dealing with employees of their own sex. In several instances women serve as assistant medical officers to prisons. The services of medical women are also enlisted as lecturers and examiners on first aid, home nursing, health, and infant care.

Openings Abroad

Colonial Office.—To those to whom oversea service appeals it offers the possibility of useful, interesting, and adequately paid work. At present there are posts for women in Malaya, and East and West Africa. The work is almost entirely hospital and maternity and child welfare work; there have been one or two specialist appointments, such as bacteriologists, and more may follow. Women have, so far, only been appointed to the lower-grade posts, but their pay is the same as that of the men in similar grades. When placed on the permanent staff they are eligible for pension.

Egypt.—Appointments in the Kitchener Memorial Hospital, Cairo, which forms part of the Clinical Faculty of the University of Cairo, are held by women. Appointments in certain dispensaries are open to medical women. There are also posts held under the education authority, chiefly school medical inspection.

India.—See note on the Women's Medical Service for India on page 483.

Mission Field.—Missionary societies offer employment to medical women, chiefly in India, China, and the Near East, where their services are urgently needed. There is a wide field of opportunity abroad for those with the missionary spirit and who are fitted for very hard work under conditions which may be difficult (see special article on Medical Missionaries at page 509).

Public Activities

Medical women are frequently appointed to serve on Royal Commissions and Government Committees dealing with medical subjects, and are also requested by them to give evidence of an expert medical nature.

Medical women have always shown considerable interest in medico-political affairs, and take an active part in the work of the British Medical Association, and with the various other societies dealing with medicine as it affects the community in general. With this end in view they also have a Medical Women's Federation, which enables them to voice a collective expression of opinion. This might otherwise be difficult to ascertain, as women are so widely scattered, as regards both their geographical distribution and their varied activities. This collective opinion of medical women has been found of great assistance by the British Medical Association and other allied societies with which it works in cordial co-operation and by whom it is frequently approached, both for information and also as a convenient means of approaching medical women as a whole.

It may be added, with regard to contributions to medical literature, that this is a branch of work in which women are more and more taking their share, and scientific and other works are frequently published by them.

WOMEN'S MEDICAL SERVICE FOR INDIA

Among careers open to medical women abroad the Women's Medical Service for India deserves honourable mention. This Service is open to fully qualified medical women of British or Indian nationality, and with the present amount of Government subsidy the number of medical officers is limited to 44.

Medical women proceeding to India to join the Women's Medical Service receive a sufficient sum for a first-class passage to India. On landing they are posted to one of the larger women's hospitals to gain Indian experience and to learn the language. For a further period they are appointed to act temporarily for medical women on furlough. They are then definitely appointed to the charge of hospitals. Private practice is allowed, provided it does not interfere with official duties. The only exception is in administrative or educational posts, when an allowance in lieu of practice is given. The amount obtained from practice varies according to the station, but in most cases it forms a fair addition to the salary, varying from £150 to £1,000 a year.

Excellent opportunities for surgery—especially gynaecological—are found in the Women's Medical Service. In the future opportunities are likely to open in connexion with maternity and child welfare. Rates of pay are as follows:

Years of Service	Oversea Allowance per Mensem	Salary per Mensem	English Equivalent* per Annum
1 to 3	Rs. 100	Rs. 450	£495
4 to 6	Rs. 100	Rs. 500	£540
7 to 9	Rs. 100	Rs. 550	£585
10 to 12	Rs. 100	Rs. 600	£630
13 to 15	Rs. 150	Rs. 650	£720
16 to 18	Rs. 150	Rs. 700	£765
19 to 21	Rs. 150	Rs. 750	£810
22 to 24	Rs. 150	Rs. 800	£855
Over 24	Rs. 150	Rs. 850	£900

* At rupee value 1s. 6d.

Furnished quarters are provided, representing an additional Rs. 150 per mensem.

The cost of living in India is much higher than formerly, but it should be possible for a medical woman (with house provided) to meet actual household expenses for about Rs. 350 per mensem, leaving the remainder of her salary for dress and personal expenses. To this must be added the necessary saving to meet additional expenses for furlough and leave spent in the hills.

Leave on average pay is earned at the rate of two-elevenths of the period spent on duty.

Study leave is granted to the extent of twelve months in the total service, and will not be granted more than twice in the course of an officer's service. During study leave an officer draws half average pay, with a study allowance at the rate of 12s. a day during the course of study. Officers of European domicile are entitled to four free return first-class passages from a port in India to a port outside India in their whole service. The first passage is not granted until after the expiry of four years' approved service, and thereafter passages may be granted at intervals of not less than four years. There is a Provident Fund to which members of the Service contribute 10 per cent. of their pay. The Service contributes another 10 per cent., which accumulates at interest and is repaid on retirement.

Admission to the Service is made by selection in India and England, preference being given to those with Indian experience. Vacancies are few. Candidates in the United Kingdom should apply to the Medical Adviser, Countess of Dufferin's Fund, c.o. The High Commissioner for India, India House, Aldwych, London, W.C.2. Candidates in India should apply to the Chief Medical Officer, Women's Medical Service, Countess of Dufferin's Fund, Simla and Delhi.

Postgraduate Study

Postgraduate students may be divided into general practitioners desirous of refresher courses, usually covering a wide field within a relatively short period of time, to bring their knowledge up to date; those who wish for instruction in special subjects with a view to obtaining one of the special diplomas or of preparing for some higher examination, perhaps with a view to promotion in one or other of the medical services, or, if already general practitioners, of adding some form of specialism to their work; and visitors, whether from the oversea Empire or from foreign countries, who wish to pursue intensive studies in special subjects or to familiarize themselves with the methods of practice in Great Britain. Further, mention may be made of medical members of the Defence Services who, for reasons similar to these, constitute an important section of postgraduate students; and of Indian and other students who, having completed the ordinary medical curriculum, wish to pursue their studies further before returning to their own countries.

It is clear that London, with the large and varied amount of material available, and with its wealth of professional skill and teaching power, offers ample opportunity for the supply of all these needs. Till recently, however, no definite postgraduate school of the general character and scope required had begun to function, though important steps had been taken to remedy this lack. There are teaching centres which have done, and are doing, admirable work, but they are widely scattered, and their efforts are limited and largely unsystematized. Two hospitals—the West London Hospital at Hammersmith, and the Prince of Wales's General Hospital at Tottenham—have for many years had postgraduate colleges attached to them. Their efforts are valuable and praiseworthy, but they can cater only for a limited number of general practitioners, and these largely drawn from those whose practices are within a relatively short distance of the schools. The general practitioner may also perhaps find a refresher course at the hospital at which he was trained held during a vacation, and other courses are organized from time to time at some of the London hospitals, general or special. The Fellowship of Medicine, too, arranges definite courses of study at individual hospitals; and at its office—generously placed at its disposal by the Royal Society of Medicine at 1, Wimpole Street, W.1—a list of hospitals, special and general, to which medical graduates may resort, with or without fee, is kept, and the names of the teachers at each hospital are available.

All these agencies and schools at present continue their activities, and it seems probable that they may be required for some time to come; but, the more unified, systematized, and comprehensive provision needed is now established at the British Postgraduate Medical School in Ducane Road, Shepherd's Bush. It is more than fifteen years since a committee, presided over by the Earl of Athlone, reported that there should be "a school attached to a hospital centrally situated in London devoted solely to postgraduate medicine as a school of the university." The school, under the auspices of the University of London and of the London County Council, was opened by King George V in 1935. The King expressed the earnest hope that the school "with its happy union of ward and laboratory, university and local authority, drawing students and teachers alike from all parts of our Empire—and I trust from regions even more widely spread—may prosper under God's blessing. May it play an imperial role in the winning and dissemination of medical knowledge and in the relief of suffering, and in enabling the doctors of all lands to come together in a task where all must be allies and helpers."

At that time the chairman of the Governing Body was the late Sir Austen Chamberlain. He has been succeeded in that office by Sir John Caulcutt. The School is at

present recognized as a constituent college of the University of London, and the London County Council has reorganized its hospital to adapt it for its enlarged purposes. It has been extended and fitted with the most modern equipment. When its two new blocks are in use it will provide 534 beds. The Dean of the School is Colonel A. H. Proctor; a distinguished body of professors and readers in several departments of medicine has been appointed; and definite courses of instruction have been successfully conducted. The number of enrolled students is as yet relatively small; and the School suffers from some disadvantages. It is somewhat remote from the university quarter, and access to it is not very convenient. Wood Lane and East Acton are its nearest railway approaches. The facilities it offers to students are not yet as well known as they should be. It may be that these things account for the somewhat disappointing progress that has yet been made towards the fulfilment of the hopes voiced by King George V; but the Governing Body and the School Council have made suitable arrangements to meet the needs of various classes of students, and it can scarcely be doubted that the unique opportunities which the School and Hospital afford will soon be fully realized. Through it London should become a world centre for postgraduate medical training.

The Governors of the British Postgraduate Medical School have entered upon negotiations with certain well-known special hospitals—the Hospital for Sick Children, Great Ormond Street, the Royal London Ophthalmic Hospital, and the National Hospital for Diseases of the Nervous System—with a view to intimate co-operation in postgraduate education.

With regard to other special fields of work, there has been a steady increase in the demand for postgraduate instruction in the psychological aspects of medicine, and this will probably continue owing to the passage of the Mental Treatment Act and other causes. An important impetus in this direction has been given by the revision of the regulations for the University of London diploma in psychological medicine. In the scope of its diploma are now included mental retardation and delinquency, and also the psychoneuroses. Systematic attempts to provide instruction in these fields are being made by at least three bodies. There are courses held at the Maudsley Hospital. Courses in mental deficiency are held once or twice yearly, organized by the Central Association for Mental Welfare in conjunction with the University of London and with the London School of Hygiene and Tropical Medicine. The Tavistock Clinic (formerly the Institute of Medical Psychology), in addition to a five weeks' introductory course beginning early in October, holds from time to time short courses of lectures for the general practitioner. The main course in psychotherapeutic theory and method now covers two years' work, and is open to a limited number of practitioners only. They are expected to give a minimum of twelve hours (on three days) in the week. The first year's work is intended to cover the ground for those desirous of practising psychotherapy, while the full course is meant for those intending to specialize in the subject. The clinic now has admirable premises at Malet Place, W.C., and such systematic teaching as that indicated has been more fully and effectively developed there and has now become very extensive and important. The course covers the requirements for the appropriate parts of the university diploma.

Instruction in all branches of preventive and of tropical medicine is now available at the London School of Hygiene and Tropical Medicine, at the corner of Keppel Street and Gower Street. This institution was opened in 1929, and has established itself as a most valuable school of the University of London in the faculties of medicine and science. Here are university chairs in public health, bacteriology, biochemistry, epidemiology, helminthology, medical protozoology, medical entomology, and medical industrial psychology.

The principal courses of study are for the university diplomas in public health, in bacteriology, in industrial psychology, and for the Diploma in Tropical Medicine and Hygiene of the English Conjoint Board. Special courses of instruction are also arranged in other subjects. The course of study for the diploma in public health comprises full preparation for both parts of the diploma examination and includes instruction in infectious disease and hospital management, and two important studies which have recently been established—namely, physiology as applied to hygiene and industry, and medical industrial psychology. It should be noted that new rules relating to this diploma have been made by the General Medical Council and come into force on October 1, 1938. The course of study for the diploma in tropical medicine and hygiene is also taken in two parts. Clinical demonstrations are afforded at the Hospital for Tropical Diseases, close by, and at other centres. With the incorporation in this school of the Ross Institute the studies in tropical hygiene have received a new impetus and direction, and the London School of Tropical Medicine may now be said to represent the confluence of three movements: that of the scheme for a central school of hygiene recommended by the Athlone Committee in 1921, that of Sir Patrick Manson and the Seamen's Hospital Society from 1899, and that of Sir Ronald Ross and his Institute at Putney.

In the provinces the Universities of Oxford, Cambridge, Birmingham, Bristol, Liverpool, Manchester, Sheffield, and Durham (at the College of Medicine, Newcastle-on-Tyne) have organized courses of postgraduate work and instruction. Liverpool University has established a regular course for ship surgeons on similar lines to that already mentioned in London. Edinburgh receives graduates from many schools in the Dominions as well as in this country. In Glasgow and in Aberdeen courses are available, and, in relation with the University of St. Andrews, courses are given by the James Mackenzie Institute for Clinical Research. At many of these centres the teaching is provided by whole-time intensive courses, by part-time courses, and by means of clinical assistantships. The Joint Tuberculosis Council has provided nomadic courses in its own special subject, and a considerable number of the Divisions of the British Medical Association are now organizing postgraduate courses in their own locality.

British Postgraduate Medical School

The British Postgraduate Medical School was incorporated by Royal Charter on July 10, 1931. It was opened by H.M. King George V, accompanied by H.M. the Queen, on May 13, 1935, in the presence of a distinguished gathering. It has been recognized as a school of the University of London, and is managed by a governing body, under the chairmanship of Sir John Caulcutt. The governing body is made up of representatives from the various departments of State interested in medical education—the Ministry of Health, various departments of State, the Royal Colleges, the Society of Apothecaries, the University of London, the London County Council, and certain co-opted members.

The School is associated with Hammersmith Hospital, one of the London County Council general hospitals. This is a modern hospital, which has been enlarged to meet the requirements of the School. The original accommodation was 388 beds, and it has been extended to 534 beds by the erection of an entirely new ward block. Two additional operation theatres of the latest design have been constructed, and, in addition, the old operation theatre, used by Sir Robert Jones during the war, has been brought up to date, and is now in use as the gynaecological operation theatre. A suite of new wards and accompanying labour rooms and nursery constitute the maternity department, and is in accordance with the latest requirements for the segregation of cases and the avoidance of infection.

Each ward throughout the hospital has attached to it, in addition to the ordinary beds, single-bedded side wards and a clinical laboratory. There have been constructed in addition special laboratories for electrocardiographic and basal metabolism observations. The kitchens have been reconstructed and a dietitian appointed. A large new block has been constructed to house the out-patient department on its ground floor, and a modern and up-to-date radiology department on the first and second floors. This department provides for both diagnostic procedures and for deep therapy. It is in all respects of the very latest design and equipment.

The School itself is housed in a block mainly devoted to administration and pathology. The medical and surgical and gynaecological departments are housed in a separate block providing clinical laboratories and rooms for senior members of the staff. The existing school block includes two lecture theatres for the use of the School. These lecture theatres are provided with an epidiascope capable of projecting large pathological specimens, a microprojector of a new and improved design, and a cinematograph. The lecture theatres seat up to 100 students, and have attached to them a suite of rooms for the use of the lecturer and accommodation of cases. There is a reference library, which is noteworthy for the large number of periodicals available for reference. These include all the important English periodicals and a selection of the more important journals published in Europe, America, and the Dominions.

The pathology department has all its laboratories in the School building. On the ground floor are provided laboratories for morbid histology and for biochemistry. On this floor is also situated the post-mortem department. On the first floor is accommodation for the professors and readers, museum, library, and the laboratories devoted to clinical pathology. The top floor is entirely occupied by the bacteriological department and the accommodation for experimental pathology. The equipment throughout these laboratories is entirely new and of modern design.

The staff of the School is organized in three divisions. First is the permanent whole-time staff. The second is the consultant staff, having regular visiting days and available for emergency calls. This consulting staff is mainly occupied in the treatment of patients, and only takes a secondary part in tuition. It has been necessitated by the fact that the School has no special departments, it being the intention of the governing body that the special hospitals already existing in London should be utilized for postgraduate students who require such instruction. The third division of the staff is the visiting staff, who conduct special courses in different groups of disease and take part in the general teaching of the School. It is hoped to include in this staff the leading teachers and authorities available in London and the provinces, and, as opportunity offers, from other parts of the world.

The permanent whole-time staff is divided into four departments—medicine, surgery, obstetrics and gynaecology, and pathology. Each department is under the guidance of a director, who is a professor appointed by the University of London. He is assisted by a reader or readers, also appointed by the University, and a varying number of assistants appointed by the governing body. In addition, each department has a resident staff.

The School provides refresher courses for general practitioners of an intensive character. These courses last for a fortnight, and are held mainly in the summer months. Not less than six such courses will probably be held during the next year. More courses will be provided if the demand should arise.

The most important part of the tuition is, however, the instruction provided for medical graduates from all parts of the world who desire to extend their knowledge in medicine, surgery, or midwifery, and for students of pathology who desire to do advanced work. In this respect the School is attempting to provide something entirely different from the work usually associated up to date with postgraduate schools; previous postgraduate instruction has consisted almost entirely of courses and lectures covering a set syllabus. Although this will form part of the instruction provided at the School, the real postgraduate instruction at Hammersmith consists in providing the students with a large amount of clinical material and encouraging them to work at it, under the tuition of well-qualified instructors. All the assistants of the School have special experience in some department of their subject, and if the student is particularly interested in that department he is attached to that particular assistant. He is allotted cases, and a definite amount of time is set apart which he can devote to the examination of these cases. He receives every assistance and such tuition as meets his personal requirements. The classes are broken up into small groups with this object, and the work from the outset is almost entirely clinical.

From time to time definite clinical lectures, carefully prepared, are given, either in the School theatres or in the clinical theatres. The students attend regular pathological conferences and radiological conferences, and conferences and discussions between the different departments. The department of pathology takes part in the clinical work of the School, and provides regular demonstrations to the students on laboratory procedures. In this way it is hoped that the students of the School will acquire a more scientific and expert approach to the problems of clinical medicine and surgery, and by attendance at the various conferences will be brought in touch with the latest advances and benefit by hearing the critical discussions on the diagnosis and treatment.

The students also attend the out-patient departments, which are purely consultative in character. The department of obstetrics and gynaecology has the advantage of being able to utilize the obstetric and gynaecological beds at St. Mary Abbots Hospital, and in this way students have a large amount of material at their disposal. In the out-patient department of obstetrics special attention is being devoted to ante-natal and post-natal work, and the prevention of maternal mortality.

The department of pathology provides instruction for students in advanced pathology in any of the three departments. It also provides accommodation for research work in pathology and for students desiring to work for the Ph.D. In addition to the weekly demonstrations on laboratory procedures, lectures on "The Place of the Laboratory in Clinical Medicine" are provided at regular intervals. The organization of a course for the Diploma in Clinical Pathology is under consideration.

The radiology department provides clinical instruction for students taking a diploma in radiology, and postgraduates who desire further instruction in radiology can be accommodated in limited numbers.

The fees for the ordinary hospital practice, including tuition, are 6 guineas for one month and 3 guineas for each subsequent month. The fee for the fortnight refresher courses is 5 guineas.

The British Postgraduate Medical School is situated in Ducane Road, Shepherd's Bush, W.12, and can be reached by rail to Wood Lane station (Central London Railway) or by No. 7 bus to Acton Vale. Information as to fees for other courses of study and further details can be obtained from the Dean.

Fellowship of Medicine and Postgraduate Medical Association

The Fellowship of Medicine arranges regular courses in general medicine and surgery, including special departments, each lasting from one to four weeks. Courses in diseases of children, diseases of the chest, heart, nervous system; dermatology; gynaecology and obstetrics; plastic surgery; proctology; orthopaedics; psychological medicine; physical therapy; urology; and practical anaes-

thetic tuition are given from time to time at the special hospitals in association with the Fellowship of Medicine. Evening clinical and pathological courses for the M.R.C.P. (four times a year) and F.R.C.S. (Primary and Final) (twice a year) are arranged also. Week-end and evening courses are arranged in many subjects. A panel of teachers is always available for clinical teaching, by arrangement with the Fellowship. Lectures and demonstrations are arranged periodically. The office of the Fellowship is, by kind permission of the Royal Society of Medicine, at No. 1, Wimpole Street, W.1 (telephone Langham 4266). The secretary is in attendance daily from 10 a.m. to 5.30 p.m. (Saturday 10 a.m. to 12.30 p.m.). The annual subscription for membership of the Fellowship of Medicine and Postgraduate Medical Association is £1 1s., which includes the *Postgraduate Medical Journal*, published monthly. Courses, lectures, and demonstrations are open only to members.

Postgraduate School of Radiotherapy

The working scheme between the London Radium Institute in Riding House Street and the Mount Vernon Hospital at Northwood, for the establishment under joint control of a Postgraduate School of Radiotherapy, continues in operation. The Dean (Sir Cuthbert Wallace) will be pleased to see prospective students by appointment. Applications for information may be addressed to the Secretary (Mr. T. A. Garner) at the School, Riding House Street, London, W.1.

West London Postgraduate College

The work of this institution is carried on at the West London Hospital, the first in London to devote its clinical material solely to the instruction of qualified medical men. The college started in 1895; it is provided with lecture, reading, and writing rooms, and accommodation of all sorts for the convenience of postgraduate students. The work of the college is eminently suitable for men in general practice and officers in the Services who wish to revive their general clinical knowledge.

Clinical teaching is carried out in the wards and out-patient department, the latter being one of the largest in London, and affording ample opportunities for post-graduates to examine patients. Operations take place at 2 p.m. daily, and there are the usual special departments. Postgraduates may be appointed to act as clinical assistants for six months, no charge being made. A special clinic for the treatment of venereal diseases (male and female) is held all day. Graduates are admitted to the work of the clinic, and certificates of satisfactory attendance and work are given.

Pathological teaching and museum demonstrations are undertaken by the pathologists.

The certificates of the school are recognized by the Admiralty, the War Office, the Colonial Office, the India Office, the University of London (for higher degrees), and the Conjoint Board. The general course is recognized as being suitable for practitioners taking a course of study under the Ministry of Health "grant-aided scheme for postgraduate study by insurance practitioners in rural areas."

Fees.—Hospital practice, including all ordinary demonstrations and lectures, £2 2s. for one week, £6 6s. for one month, £9 9s. for two months, £12 12s. for three months. Instruction in the administration of anaesthetics is given at the rate of £4 4s. a month.

A prospectus can be obtained on application to the Dean, West London Postgraduate College, Hammersmith Road, W.6.

North-East London Postgraduate College

The headquarters of this postgraduate school are situated at the Prince of Wales's General Hospital, Tottenham, N.15, in the midst of this densely populated North London district. It contains 238 beds, and is within a few minutes' walk of South Tottenham Station on the London Midland and Scottish Railway, and Seven Sisters and Tottenham Hale Stations on the London and North-Eastern Railway. It is readily accessible by electric tram from Manor House and Hackney, and from Dalston, Edmonton, and other parts of North London. The North Middlesex Hospital, Edmonton, N.18, with upwards of 1,000 beds, has, under a recent arrangement, taken part in the clinical teaching.

The college is in association with the Fellowship of Medicine and Postgraduate Medical Association, and is recognized by the Admiralty and India Office for the purpose of study leave, and by the University of London as a place for advanced study for the M.D. and M.S. degrees; the course of practical teaching of bacteriology is approved by the University of Cambridge for its D.P.H., and there are ample arrangements for the convenience of men who are thus working, or who, being in active practice, are desirous of getting themselves into touch with modern methods. The hospital affords excellent facilities for medical practitioners who wish to take part for a time in general hospital work, or to obtain special instruction in the several branches of medicine and surgery. Throughout the sessions, into which the year's work is divided, clinics, lectures, and demonstrations are given. Operations are performed every afternoon except Saturday. Special vacation or intensive courses are held at intervals. The winter session will open about the middle of September for clinical teaching.

Fees.—For the hospital practice in general medicine or surgery the fee is 5 guineas for three months or 2 guineas for one month. Provided there is accommodation in the special departments, the fees are: eye department 3 guineas; gynaecological department 5 guineas; ear, nose, and throat department 5 guineas for three months. All departments—the fee is 3 guineas for one month, 6 guineas for three months, 10 guineas for a year, and 15 guineas for a perpetual ticket. Courses in practical anaesthetics are not included in the above, and a fee of £4 4s. per month is charged for this work. For special tuition in any subject the fees are arranged with the member of the staff concerned in consultation with the Dean.

Additional information can be obtained from the Dean of the Postgraduate College, at the Prince of Wales's Hospital.

West End Hospital for Nervous Diseases

The annual out-patient attendance is between 38,000 and 40,000 at the out-patient department, Welbeck Street, W.1. The in-patient department, Outer Circle, Gloucester Gate, Regent's Park, provides 76 beds, including 25 cots for children, and is fully equipped with pathological, *x*-ray, and other special departments.

The clinical and teaching facilities of the hospital fulfil the requirements of the examining bodies for the Diploma in Psychological Medicine, and for the London M.D., Part III. Attendance on the general practice of the hospital is open to postgraduates. There are opportunities for personal examination of cases. In addition, systematic courses of instruction in neurology and in related subjects are held throughout the year. Special courses are given for the D.P.M. and for the M.R.C.P. Tuition for senior undergraduates is also arranged.

The courses of instruction in neurology consist of out-patient demonstrations, ward rounds in the in-patient department, and lecture-demonstrations by the physicians and surgeons; clinical demonstrations of psychological cases are given by members of the psychiatric department and the child guidance unit; also pathological discussions. Of the related subjects, demonstrations on the new logical aspects of their subjects are given in radiology, ophthalmology, orthopaedics, physical medicine, and oto-rhino-laryngology. A department of clinical research has been founded, and any qualified persons desirous of working in this department should apply to the director. The Savill Memorial Prize (value £15 and medal) is offered biennially for competition

amongst postgraduate students of the hospital. Honorary clinical assistantships are available in the out-patient department, and application for these should be made to the House Governor, to whom application should also be made for particulars of the courses of instruction.

Manchester Postgraduate Facilities

Courses in preparation for the diplomas in psychological medicine, in public health, bacteriology, and veterinary State medicine are arranged. There are facilities also for obtaining a certificate in venereal diseases. A limited number of clinical assistantships at the discretion of the hospitals are offered in the medical, surgical, and special departments of the Manchester Royal Infirmary, the Ancoats Hospital, and certain special hospitals for one, two, or three months, or longer. A clinical assistantship at the Radium Institute for three months is offered. Clinical teaching for postgraduates is given each Thursday during university terms by the honorary staff at Ancoats Hospital; no fee charged.

Postgraduate Courses at Bristo

The University of Bristol provides courses of postgraduate study for practitioners. Details of set courses at the Royal Infirmary and General Hospital are announced locally. In addition, practitioners may become clinical assistants in medicine, surgery, or special subjects for periods of a month or more.

Daily Postgraduate Study.—For those who are able to devote several hours each day to hospital practice the university offers special facilities for postgraduate work. Qualified medical practitioners may be appointed as clinical assistants for a period of one or more months. They may act as assistants, if times permit, in more than one department and in any of the hospitals during their period of study. They will be entitled to the use of the clinical laboratories and medical library, and have the right to attend in all departments, including operations, postgraduate and ordinary clinical demonstrations, and postmortem examinations.

All inquiries and applications for admission should be addressed to the Director of Postgraduate Studies (Clinical Section), Department of Medicine, University of Bristol.

Postgraduate Courses at Newcastle

The following postgraduate courses can be taken at the Medical School, King's College, Newcastle-upon-Tyne, formerly the University of Durham College of Medicine (University of Durham).

1. General courses in clinical medicine, surgery, and pathology at the Royal Victoria Infirmary, meeting once weekly for ten weeks. One course will be held from October to December, and one from April to June.

2. Special courses of clinical instruction meeting once weekly for ten weeks in the following subjects: gynaecology, diseases of the eye, diseases of the throat, nose, and ear, diseases of the skin, venereal diseases, neurology. Special courses in midwifery will be held at the Princess Mary Maternity Hospital.

3. An intensive course of fourteen days' duration in the summer vacation.

4. In addition to the regular postgraduate courses, practitioners may attend the ordinary medical and surgical practice of the Royal Victoria Infirmary, and also at the Princess Mary Maternity Hospital, for specified periods.

5. Classes are held at the Newcastle General Hospital for clinical instruction in medicine and surgery, or lecture-demonstrations, every Sunday morning during term. There is no fee, and all medical practitioners are invited to attend.

6. General and special courses in dental surgery are also provided in the Dental Department.

Postgraduate Study in Cardiff

Certain courses of postgraduate study are given during the year, and facilities may be offered to graduates in medicine and other duly qualified persons to carry out research work in the different departments of the Medical School. Research Scholarships are available ranging in value from £150 to £250 per annum. Further information regarding these is given under the heading "Research Scholarships" in the article on the University of Wales (p. 456).

Edinburgh Postgraduate Courses

In connexion with the University and Royal Colleges postgraduate courses are arranged every year, from about the middle of July to about the middle of September, comprising: (*a*) a course in obstetrics and gynaecology, held from July 12 to July 31; (*b*) a general practitioner course; (*c*) a general surgical course. Courses (*b*) and (*c*) extend for four weeks from August 16 to September 11. Similar courses are arranged each year.

The course in obstetrics and gynaecology includes instruction in clinical midwifery and clinical gynaecology, obstetrical and gynaecological anatomy, physiology, and pathology, ante-natal and post-natal clinics, and the care of the newborn infant, etc.

The general practitioners' course includes lecture-demonstrations, and, where possible, practical instruction on medical anatomy, medical sideroom work, examination of the blood, *x*-ray and electrical therapy, morbid anatomy, and post-mortem examination; clinical instruction in medicine, surgery, gynaecology, child life and health, diseases of the skin, and infectious diseases; and special instruction in the diseases and methods of examination of the nervous, circulatory, respiratory, alimentary, and renal systems, and in diseases of the ductless glands. The general surgical course includes lecture-demonstrations on surgical anatomy, surgical pathology, and surgical *x*-ray diagnosis; clinical instruction in surgery at the Royal Infirmary and Royal Hospital for Sick Children; clinical instruction in venereal diseases; surgical out-patients, surgical and gynaecological operations, and special instruction in abdominal, genito-urinary, and other branches of surgery.

A course on internal medicine to be given from October 18 to December 10 has also been arranged. There will be four hours co-ordinated teaching daily throughout the course. Diseases of the various systems will be dealt with during successive weeks—for example, the first week will be devoted to cardiology. 10 a.m., methods of diagnosis; 11 a.m., clinics on cardiac cases; 12 noon, ward work; 2 p.m., correlated demonstrations on clinical pathology, radiology, etc.; 4 p.m., physiology of the circulation; 7 p.m., ward work. The graduates will be apportioned for ward work to the eight physicians on the staff of the Royal Infirmary. The attendance will be limited to thirty-two.

A series of clinical discussions, open to all graduates, is arranged on subjects of general interest. Among the special courses also arranged at various times of the year are: examination of the blood, diseases of the ear, nose, and throat, ophthalmoscopy, venereal diseases, *x*-ray physics and electrotechnics, tuberculosis, ultra-violet radiations and their uses, the interpretation and significance of modern diagnostic methods, surgical pathology, clinical surgery (including radiology), clinical medicine (including radiology and child life and health), urological surgery and treatment of fractures, neurological surgery, orthopaedic surgery, endocrinology, diseases of the nervous system, urology, modern methods of anaesthesia.

Particulars regarding the courses, dates of commencing, fees, etc., may be had on application to the Honorary Secretary, Postgraduate Courses in Medicine, University New Buildings, Edinburgh.

Postgraduate Medical Teaching in Glasgow

Organized postgraduate medical teaching is available in Glasgow under the auspices of the Postgraduate Medical Association. This association represents practically all the teaching institutions in Glasgow and the various teachers giving postgraduate instruction, and its business is managed by a board elected periodically by them. The chairman of the board is Professor Archibald Young. During the winter months special courses in vario

subjects are conducted. From November till May there is a series of weekly demonstrations and lectures, specially designed for local practitioners. Clinical courses are carried out during the summer months, and arrangements have also been made whereby a limited number of graduates may become attached to wards or out-patient departments nominally as clinical assistants for definite periods throughout the year. As such they work under the direct supervision of the physician or surgeon in charge, and carry out such detailed investigations as directed.

A general medical and surgical course is held each year during the last two weeks of August and the first two weeks of September, which is arranged to include most of the subjects of interest to the general practitioner. This year the course is being conducted from August 16 to September 10. The forenoons are occupied with general medicine and surgical diagnosis and minor surgery, in the Royal Infirmary and in the Victoria Infirmary. In the afternoons special subjects are dealt with in the special hospitals and in the special departments of the general hospitals, two subjects being considered each afternoon.

Further information may be had on application to Dr. James Carslaw, Secretary, Postgraduate Medical Association, 9, Woodside Terrace, Glasgow, C.3.

Dublin Postgraduate Course

The usual three-weeks postgraduate course will be held in Trinity College, Dublin, from September 20 to October 8, and, as on former occasions, it will consist of clinical instruction, formal lectures, and laboratory work.

Tropical Medicine

There are large and important Schools of Tropical Medicine in London and Liverpool, and the Colonial Office expects all nominees for the Colonial Medical Service to pass through one or other of the two schools mentioned before their appointments are confirmed, and commercial firms engaged in tropical enterprise commonly demand from medical applicants for employment corresponding evidence of special knowledge. Information with regard to these schools and diplomas and degrees is given in the paragraphs printed below. The University of London alone gives a degree (M.D.) in Tropical Medicine, and this, being an "internal degree," can only be taken by students who are medical graduates of that university. Diplomas in Tropical Medicine or Hygiene are granted by the universities of Edinburgh and Liverpool, and by the Conjoint Board of the Royal College of Physicians of London and the Royal College of Surgeons of England.

Diplomas and Degrees

LONDON UNIVERSITY.—Tropical medicine is one of the six branches in which the M.D. degree may be obtained. Candidates must normally have taken the M.B., B.S. degree not less than two years previously and must subsequently have attended a course of one academic year in tropical medicine at an approved school, or must have practised for two years in a region where tropical diseases prevail. In exceptional circumstances candidates may enter for the M.D. examination one year after taking the M.B., B.S. degree.

THE CONJOINT BOARD IN ENGLAND.—This body grants a diploma in tropical medicine and hygiene to candidates after an examination held in the months of January, April, and July. New regulations are in force, and twenty-one days' notice in writing instead of fourteen days is now required of candidates for all examinations. The hospitals and laboratories recognized for this diploma are the London School of Hygiene and Tropical Medicine, the Royal Army Medical College, the Liverpool School of Tropical Medicine, the School of Tropical Medicine, Calcutta, and the Usher Institute, Edinburgh. Particulars and conditions of admission to these examinations, fees, etc., may be obtained from the Secretary, Examination Hall, Queen Square, London, W.C.1.

UNIVERSITY OF LIVERPOOL.—A diploma in tropical medicine is given by this university to candidates possessing a recognized medical qualification who have attended the courses provided by the Liverpool School of Tropical Medicine and who have passed the examination held thrice yearly by the university examiners. The subjects of examination are: (*a*) parasitology; (*b*) entomology; (*c*) tropical medicine, including actiology, symptoms, pathology, diagnosis, and treatment of tropical diseases. Fee for the course, £21. A diploma in tropical hygiene (D.T.H.), open to the holders of the D.T.M., has also been established. The examination is held twice yearly by the university examiners. The subjects of examination are tropical hygiene (including sanitary engineering, vital statistics and epidemiology, and applied parasitology and entomology); practical sanitation, bacteriology, chemistry (including meteorology and climatology). Fee for the course, £12 16s. Further information can be obtained from the Dean of the Faculty of Medicine, University of Liverpool.

UNIVERSITY OF EDINBURGH.—Candidates for the diploma in tropical medicine and hygiene granted by the University of Edinburgh must be graduates in medicine and surgery of that university, or hold corresponding degrees or qualifications registrable with the General Medical Council of Great Britain, or of such other universities or medical schools as may be recognized for the purpose by the University Court. The course of instruction, which commences in October, extends over two terms. The examinations (Part I and Part II) are written, oral, and practical, and are held at the end of the courses. Candidates, on the first occasion of presenting themselves for examination in either part, are required to appear for all the subjects of that part. Those who fail to pass the entire examination in either part within a period of twelve months after the first appearance are required to reappear for all the subjects. The university is included in the list of institutions whose courses of instruction in tropical medicine may be taken by officers on appointment to the Colonial Medical Services or during study leave. Full particulars can be obtained from the Dean of the Faculty of Medicine, Edinburgh.

SCHOOLS

London School of Hygiene and Tropical Medicine (University of London)

(INCORPORATING THE ROSS INSTITUTE)

The courses of study in all branches of the work of the School will recommence in the autumn in the premises in Keppel Street (Gower Street), the gift of the Rockefeller Foundation, which has excellent laboratories and research rooms, a fine lecture theatre and classrooms, library, and museum.

The course of instruction for the diploma of the Conjoint Board in tropical medicine and hygiene is divided into two parts: Part I (three months), and Part II (two months). The examinations by the Conjoint Board will follow closely upon the end of the corresponding course of study. This revised course is recognized by the University of London as a course for associate students.

The dates of the courses for the session 1937–8 are:

Part I.—September 27 to December 17, 1937; January 3 to March 25, 1938; April 4 to June 24, 1938.

Part II.—January 17 to March 18, 1938; April 19 to June 17, 1938.

The course of instruction under Part I includes clinical demonstrations, applied pathology, and medical zoology. Part II comprises instruction in tropical hygiene, including, in relation to hygiene, bacteriology, entomology, and vital and medical statistics; and [illegible] tions.

Various short courses of instruction are also provided, and special arrangements are made in the case of students who are unable to attend at the beginning of a course.

The instruction in the division of clinical tropical medicine is given by the medical staff of the Hospital for Tropical Diseases and by visiting lecturers.

A whole-time course of study for the diploma in public health begins on September 28, and will extend over a period of nine months. It is arranged in compliance with the requirements of the General Medical Council, and students taking the course will be able to proceed to the academic diploma in public health of London University. The curriculum has been planned on very practical lines, and includes, in addition to work with medical officers of health in two selected areas, a large number of visits to places of public health interest. A series of special lectures, given by eminent authorities, is open to members of the medical profession as well as to students of the school. The London County Council, the City of London, and various other bodies have placed their resources at the disposal of the school for teaching purposes.

The course of study for the University of London diploma in bacteriology covers a period of one academic year beginning in October. Special three-monthly courses will be given in epidemiology and vital statistics. Courses are arranged in psychology and physiology applied to industry.

Inquiries with regard to all the above-mentioned courses should be addressed to the Secretary, London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1.

University of Edinburgh

A course of instruction for the diploma, comprising a primary and a secondary course, is given during the autumn and spring terms (October to March), and includes tropical hygiene, bacteriology, entomology, and parasitology, diseases of tropical climates (systematic and clinical), tuberculosis, and venereal diseases. The university is included in the list of institutions whose courses of instruction in tropical medicine may be taken by officers on appointment to the Colonial Medical Services or during study leave. Full particulars can be obtained from the Dean of the Faculty of Medicine.

Liverpool School for Tropical Medicine

This school is affiliated with the University of Liverpool. The university grants diplomas in tropical medicine (D.T.M.) and in tropical hygiene (D.T.H.).

Two full courses of instruction, each lasting about eleven weeks, are given every year for the D.T.M., commencing respectively September 30, 1937, and January 3, 1938, and two courses for the D.T.H., beginning on January 6 and April 21, 1938. The D.T.H. can only be taken by those who have obtained the D.T.M. Students who do not desire to take the diploma examinations held by the university at the end of each term are given a certificate if attendance has been satisfactory.

Fees.—(1) For the D.T.M. course, 20 guineas; for the D.T.H. course, 10 guineas. (2) For the diploma examinations, 5 guineas. An extra charge of one guinea is made for the use of a microscope if required.

The laboratories of the school adjoin the university and the tropical ward of the Royal Infirmary. The dimensions of the building are 162 feet in maximum length by 84 feet in width. In addition to the basement, in which are accommodated the photographic department and large storage rooms, there are four floors. The ground floor has: (1) lecture theatre, with accommodation for about seventy students; (2) library; (3) a spacious museum with preparation room adjoining. The first floor has twelve rooms, in which are housed the departments of tropical medicine, tropical hygiene, and entomology. The second floor has the main class laboratory, 69 feet by 58 feet, excellently lighted; and three other rooms, devoted to the department of parasitology. The third floor has a large research laboratory and two research rooms. On the roof is an insectarium, a mosquito-proof house, and other accommodation.

Since its foundation the school has dispatched to the Tropics thirty-two scientific expeditions, many of the workers having been taken from among its students. The work done by the staff has been published in twenty-four special memoirs; in the *Annals of Tropical Medicine and Parasitology*, issued by the school; and in numerous articles in the scientific press.

The school also has a laboratory in the Tropics: the Sir Alfred Lewis Jones Tropical Laboratory in Sierra Leone, which was opened on January 10, 1922, and is staffed by the school. Further information may be obtained from the Laboratory Secretary, School of Tropical Medicine, Pembroke Place, Liverpool, 3.

Psychological Medicine

Medical men recently qualified, or whose experience with mental cases has been slight, are not infrequently at a loss when confronted with mental illness. They feel most assured when such illness is clearly the outcome of some definite bodily derangement, either as its accompaniment or its sequel, for they realize that its successful treatment will depend upon the recognition of the underlying malady. In this connexion one calls to mind the great diversity of delirious states, short or prolonged, induced by cerebral contusion, by bacterial invasion, by poisons from without or toxins from within the system; the neurological complications of syphilitic infections—for example, meningo-vascular syphilis and syphilitic encephalitis, generally known as general paralysis of the insane; the sequelae of encephalitis lethargica; the psychological concomitants of Graves's disease, myxoedema, pernicious anaemia; the "symptomatic" epilepsies, cardiovascular disease, and many more. In such cases no therapy directed towards the superficial symptoms alone can ultimately prove of avail; it must be radical, attacking the seat of the disease.

Mental illnesses of this nature do not bulk largely in the statistics of mental hospitals, whose numbers are of course swollen by the preponderance of those afflicted with chronic maladies, such as dementia praecox, the paraphrenias, and recurrent manic-depressive episodes. These psychoses may well be of organic derivation, but their treatment by interference with organic processes (for example, hypoglycaemic shock) though occasionally successful does not rest upon any sure scientific foundation. Hence, in the main, treatment is along social lines, consisting as it does of measures to prevent deterioration, to re-establish "contact" with life by promoting suitable interests and correcting maladjustments. Eventually, it may be hoped, scientific therapy will replace social therapy in these disorders.

Often enough mental illness is no inevitable accompaniment or aftermath of bodily disease, even though such exists, but may arise accidentally, as it were, as a by-product, produced by psychological repercussions, the stirring up of fears and anxieties, disappointments and animosities with which the illness has become inextricably interwoven. Such cases abound in practice as hypochondrias, and hysterical and other psychoneurotic states. Their understanding is only to be attained by the discovery of the obscure satisfaction their illness affords such patients; and, as in the pure psychoneuroses, knowledge of the psychological structure of the reaction is a *sine qua non* of a scientific therapy. Constitutional tendencies doubtless provide the soil for the production of both psychoses and psychoneuroses, and may be of such a kind as to be clearly recognizable as congenital mental defectiveness. A knowledge of psychological medicine to be requisite must embrace an understanding of the mental maladaptations met with in these three great groups. A practical acquaintance with all of them will prevent many diagnostic and therapeutic errors.

All too often a patient meets with some calamity, with all its attendant distasteful publicity, which a knowledge

of the practical aspects of mental disease might well have obviated. The treatment of psychotics is the province of the psychiatrist, but their early recognition is of supreme importance; and a working knowledge of such states will afford to the practitioner the means of their detection at a stage when curative measures are most likely to meet with success. Sufferers from one or other of the functional nervous disorders are innumerable, and too many of them pass from doctor to doctor unassuaged. The intervention of the specialist may be necessary in the treatment of the severer forms of hysteria and neurosis; but many practitioners have now acquired a sufficient knowledge of such states to be able to carry out a thorough and effective system of treatment themselves.

Mental deficiency cannot escape detection in its extremer forms, but numerous higher-grade defectives, many of whom are a menace to the community by reason of their criminal propensities, escape recognition; and especially must the student who proposes to take up a career in the school medical service or in the prison service make sure that he is thoroughly grounded in this subject.

It is generally assumed that the mental expert is equally well acquainted with each of these departments of psychological medicine—the psychoses, the psychoneuroses, and mental deficiency. This, however, is seldom the case. In the past there has been too rigid a specialization, largely the outcome of administrative requirements. Recently, owing to the establishment of mental out-patient clinics and the coming into force of the Mental Treatment Act, which gave sanction to the admission of voluntary patients into public mental hospitals, the psychiatrist's experience has been considerably enlarged; and his province has been still further widened where the authorities have elected to place the selfsame physician in charge of both the psychiatric and the mental deficiency units. It is to be hoped that this process of co-ordination will continue, and that it will eventually embrace the systematic psychological examination of prisoners or, better still, of accused persons awaiting trial.

However that may be, the medical student intending to devote himself to psychiatry will be well advised to neglect no opportunity of furthering his acquaintance with every branch of psychological medicine.

Mental Hospital Appointments

Those who take up psychiatry as a career work as medical officers of public or private mental hospitals or similar institutions. Except in the larger institutions, such as those under the control of the London County Council, where a number of the medical officers are allowed to live out if married, the medical staff are resident officers, having board, lodging, etc., either in the hospital itself or a residence in the grounds. Junior assistant medical officers receive about £350 to £450 per annum, and senior assistant medical officers about £500 to £700, in both cases with board, lodging, laundry, etc., in addition; if married, the board, etc., is commuted for cash. As the mental hospitals are under local control the salaries vary much in different mental hospitals. Medical superintendents, whose pay commonly ranges between £800 and £1,500 per annum, are provided with a house in the grounds of the hospital, and draw various allowances.

Since the passing of the Asylums Officers Superannuation Act of 1909, doctors on the established staff of a public (county or borough) mental hospital, by paying as contributions 3 per cent. of the value of their appointments, may retire at the age of 55 (provided that they have completed twenty years' service), on a pension computed at the rate of one-fiftieth of their salary and emoluments for each completed year of service; but inasmuch as the benefits of this Act are restricted to the public mental hospitals and are forgone on transfer to private or chartered mental hospitals, and the provision for widows is inadequate and uncertain, less inducement is offered than might be to joining the service.

Appointments to the public mental hospitals are made by the visiting committees. Promotion tends to be slow and uncertain. The higher positions are not always advertised: but in recent years there has been a general improvement in the conditions of service.

Mental hospitals are fast developing an atmosphere approximating more closely to that of the general hospitals. Whilst routine, administrative and clerical, necessarily bulks largely in mental hospital duties, there is ample material, time, and scope for purely medical work and research, and there is no branch of medicine in which research is more needed.

Instruction in Mental Disorder

Though at the present time the instruction given to the student is scarcely adequate to supply the knowledge of mental disorder requisite for the needs of the general practitioner, the facilities for the study of psychological medicine in the general hospitals are now much greater than in former years. Thus many of the teaching hospitals have out-patient departments for the treatment of mental cases, and in some of these hospitals special lectures are given in psychopathology. These facilities need not be utilized by the student, however, and the compulsory part of the unreformed curriculum is generally confined to formal lectures and a few attendances at some mental hospital. Here the student is apt to see mainly the advanced states of mental disease, and is likely to gain the impression that mental disorder is necessarily related to segregation and custody. We would therefore impress upon him the importance of attending the out-patient department for mental disorders, where he will be able to observe the mild and early cases such as he will hereafter meet with in general practice.

At Guy's and at the Middlesex Hospital a small number of beds are allocated for the treatment of patients suffering from mental disorder; and we learn that in St. George's Hospital, when rebuilt, some fifty beds will be provided for cases which will include psychotic patients as well as those who suffer from psychoneurotic ailments. This is a bold and enlightened policy, and one which will certainly prove of inestimable benefit; for quite apart from therapeutic advantages it will enable the student to gain true insight into the relation between mental disorder and medicine as a whole, and he will realize that it is a form of illness to be studied with other diseases and to be treated along similar lines.

In London postgraduate courses of instruction of a comprehensive kind are given at the Maudsley Hospital, Denmark Hill; and at the National Hospital, Queen Square, courses are arranged to meet the requirements for the diploma in psychological medicine in regard to nervous diseases. Besides its ordinary postgraduate teaching in neurology the West End Hospital for Diseases of the Nervous System holds courses on common disturbances of the nervous system, and provides instruction in neurology for the D.P.M. Courses in mental deficiency are arranged by the University of London. There are also postgraduate courses at the various universities which grant diplomas of psychological medicine or of psychiatry.

There are various facilities for instruction in psychotherapy and for the study of the psychoneuroses. The Institute of Medical Psychology in London has systematic courses of instruction dealing especially with the minor forms of mental disorder which are not usually met with in the mental hospitals. At the London Child Guidance Clinic fellowships are open to medical graduates who hold a diploma in psychological medicine.

Diplomas

Those who are taking up psychiatry as a career will find it essential to obtain a diploma in psychological medicine. Such a diploma is not at present compulsory for a permanent position on the staff of all mental hospitals, but it will probably become so in course of time, just as it is now essential to obtain the D.P.H. if a career in public health is contemplated. Psychiatry is one of the branches of medicine which candidates for the M.D. degree of the Universities of London and Edinburgh can take up, and, in addition, diplomas in psychological medicine (D.P.M.), to which reference has been made, can be obtained from the Universities of London, Edinburgh, Durham, Leeds, Manchester, Dublin, and the National University of Ireland, and from the Conjoint Board in England. The requirements for a diploma differ to some extent in the various universities and colleges.

UNIVERSITY OF LONDON (D.P.M.)

The diploma awarded by the University of London certifies that the candidate has passed the examination in psychological medicine with special knowledge of one or other of the two branches, either psychiatry or mental deficiency, special provision being made for this in Part B of the examination. The examination consists of two parts, A and B; Part A must be passed before Part B is taken. It is held twice in each year—Part A in March and October, and Part B in April and November. Part A consists of anatomy, histology, and physiology of the nervous system (one paper and a practical examination), and psychology (one paper and an oral examination). Part B consists of neurology (one paper and a clinical and an oral examination) and psychological medicine (two papers and a clinical and an oral examination). Paper I tests the candidate's general knowledge of both mental diseases (psychiatry) and mental deficiency, and Paper II is a special one consisting of two separate alternative sections, the first section relating to mental diseases (psychiatry), and the second section to mental deficiency. A copy of the Regulations and of the Syllabus of Study will be sent on application to the University Extension Registrar, University of London, W.C.1.

CONJOINT BOARD IN ENGLAND (D.P.M., R.C.P. AND S.ENG.)

Both parts of the examination are held in June and December. The examination comprises the following subjects, with special regard to their relation to psychological and general medicine:—Part I: (*a*) anatomy (macroscopic and microscopic) and physiology of the nervous system; (*b*) psychology. Part II: (*a*) clinical neurology and neuropathology; (*b*) psychological medicine, including psychoneuroses and mental deficiency, and their legal relationships. The examination will be written and oral in Part I, and written, oral, and clinical in Part II. No special certificates of study are required for Part I, but before entering for Part II candidates must produce certificates of: (*a*) having attended clinical instruction for at least two months at a recognized hospital for nervous diseases, or in the department for nervous diseases of a recognized general hospital; (*b*) having held a resident or whole-time appointment at an institution for mental diseases where clinical instruction is given, recognized for the purpose, for a period of six months, or having attended clinical instruction in psychological medicine at a recognized institution during twelve months. Further particulars may be obtained from the Secretary, Examination Hall, 8-11, Queen Square, London, W.C.1.

UNIVERSITY OF EDINBURGH (DIPL. PSYCH.)

Candidates for the diploma must have held subsequent to graduation: (*a*) a resident appointment for one year in a hospital for mental disorders approved by the Faculty; or (*b*) a six months' appointment as above, and six months' practical study of nervous diseases in a special or general hospital approved by the Faculty. The examination comprises:—Part I: (*1*) anatomy of the nervous system: (2) physiology of the nervous system; (3) psychology. Part II: (1) neuropathology; (2) psychiatry and clinical psychiatry; (3) clinical neurology. Further particulars may be obtained from the Dean of the Faculty of Medicine, the University of Edinburgh.

UNIVERSITY OF LEEDS (D.P.M.)

The examination is in three parts, and is written, oral, and practical. Subjects of examination:—Part I: (1) the development, anatomy, and histology (human and comparative) of the nervous system; (2) the physiology of the nervous system, and of the organs of special sense; (3) general psychology. Part II: (4) the pathology of the nervous system. Part III: (5) clinical psychiatry; (6) experimental and morbid psychology; (7) (*a*) clinical neurology; (*b*) mental hospital administration; (c) medico-legal aspects of insanity. Candidates, in order to pass, must satisfy the examiners in the practical and clinical parts of the examination in Parts II and III respectively. They may present themselves for the three parts of the examination separately, or at the same time, provided that no candidate shall be allowed to pass in Part II unless he has already passed in Part I, or in Part III unless he has already passed in Parts I and II. Evidence must be produced by candidates as to attendance of approved courses of instruction before they submit themselves to Part I of the examination. Particulars may be obtained from the Academic Sub-Dean, School of Medicine, Leeds.

UNIVERSITY OF MANCHESTER (D.P.M.)

The examination is in two parts. Before presenting themselves for either part of the examination candidates must produce evidence of having attended, subsequent to qualification, certain approved courses of instruction, particulars of which may be found in the prospectus of postgraduate courses, and must also have resided for at least six months in a Mental Hospital. The course of study extends over a period of three university terms, two of which must be taken in the university: the remaining term may be taken at the university, or at some approved institution. The subjects of examination are:—Part I: (1) a written and practical examination on the development, anatomy (human and comparative), and physiology of the nervous system; (2) a written and practical examination in psychology (theoretical and experimental). Part II: (1) a written and practical examination in pathology in relation to the nervous system; (2) a written, clinical, and oral examination in psychological medicine; (3) a clinical and oral examination in clinical neurology. For further information application should be made to the Dean of the Medical School, the University, Manchester.

UNIVERSITY OF DURHAM (D.PSY.)

The examination for the Diploma in Psychiatry consists of two parts. Part I: anatomy, physiology, pathology, and bacteriology; Part II: psychology and experimental psychology, neurology and psychiatry (systematic and clinical); and candidates may present themselves for the whole examination or for either part separately. Particulars of the courses of instruction may be had on application to the Dean, the Medical School, King's College, Northumberland Road, Newcastle-upon-Tyne.

UNIVERSITY OF DUBLIN DIPLOMA

A postgraduate diploma in psychological medicine is conferred upon registered medical practitioners who have held a resident medical appointment at a recognized institution for the treatment of mental diseases for twelve months, or who have held such an appointment for six months and have attended clinical instruction at an approved institution for six months. Particulars of special courses of instruction may be obtained from the Registrar of the School of Physic, Trinity College, Dublin.

NATIONAL UNIVERSITY OF IRELAND (D.P.M.)

The National University of Ireland grants a diploma in psychological medicine. Application should be made to the Registrars of the Constituent Colleges, University College, Dublin; University College, Cork; and University College, Galway, for all information as to courses, etc.

CONJOINT BOARD IN IRELAND (D.P.M.)

There are two examinations in connexion with the diploma in psychological medicine. Part I consists of (*a*) anatomy and physiology of the nervous system, (*b*) psychology. Part II: (*a*) neurology, including clinical and pathology neurology; (*b*) psychiatry, or psychological medicine, including its legal relationships. Fees £6 6s. for each part.

Courses of Instruction

MAUDSLEY HOSPITAL, LONDON

A course of instruction for the Diploma in Psychological Medicine is given annually at the Maudsley Hospital, Denmark Hill, from January to May inclusive, the details of the last course being as follows. The course consisted of two parts. In the first part lectures on the anatomy of the nervous system were given by Professor Le Gros Clark, with practical instruction by Mr. C. Geary. A course of lectures on the physiology of the nervous system, with demonstrations in physiological psychology, was given by Professor F. Golla; a series of lectures on biochemistry in relation to the nervous system by Dr. S. A. Mann; on mental mechanisms by Professor E. Mapother; on theoretical and practical psychology by Dr. J. M. Blackburn; and on the practical application of intelligence tests by Dr. C. J. C. Earl. For the second part of the course lectures on the general principles of psychiatry, with a series of clinical demonstrations on the same subject, were given by Professor Mapother; on psychopathology and the principles of psychotherapy by Dr. Bernard Hart; on general treatment by Dr. T. Tennent; on laboratory methods by Dr. Mann; and demonstrations on the pathology of the central nervous system by Mr. Geary. Dr. Tredgold lectured on mental deficiency, Dr. M. Creak on mental abnormalities of children, Dr. East on crime and insanity, and Sir Hubert Bond on the legal relationships of insanity. Dr. S. Nevin gave instruction on clinical neurology at the Hospital for Nervous Diseases, Maida Vale, and Mr. Foster Moore on eye changes as applied to psychiatry. Dr. A. J. Lewis gave a series of demonstrations on the psychoneuroses and affective disorders. During the course a series of clinical demonstrations were arranged at the various London county mental hospitals and institutions for mental defectives. The fee for the whole course (Part I and Part II) was 15 guineas, or for either part separately 10 guineas; for one single series of lectures in Part I the fee was 4 guineas, and in Part II 2 guineas. Inquiries as to lectures, etc., should be addressed to Professor Golla, Honorary Director of the Medical School, Maudsley Hospital, Denmark Hill, S.E.5, and as to clinical facilities to Professor Mapother, the Medical Superintendent of the hospital.

BETHLEM ROYAL HOSPITAL

The Bethlem Hospital is situated at Monks Orchard, Eden Park, Beckenham, Kent, where every facility is available for the clinical study of nervous and mental disorder. The classification of patients is a prominent feature in the administration of the hospital, and treatment in all its modern and specialized aspects can be carried out at the Lord Wakefield of Hythe Treatment and Research Laboratories. Two courses of lectures and practical instruction for the Diploma in Psychological Medicine are given each year, in spring and autumn. These are of an intensive character, one commencing in September and completed in early December, and the other commencing in the middle of January and completed in the middle of April. Each course consists of two parts: Part A includes lectures and demonstrations on the anatomy, histology, and physiology of the nervous system, with lectures on psychology and demonstrations in experimental psychology. Part B comprises lectures and clinical demonstrations in psychology, including lectures and demonstrations in the morbid anatomy of the nervous system; a series of lectures, with clinical demonstrations, on different branches of psychological medicine; and lectures, with clinical demonstrations, on mental deficiency. Entrants for the course who pay a composition fee of 15 guineas may, if due notice is given, attend either Part A or Part B of one course and postpone the other part until the next session. An entrant who wishes to attend one part only pays a fee of 10 guineas. An entrant who takes the complete course can attend the general clinical practice of the hospital, on payment of 5 guineas for six months, or 10 guineas for one year, but an entrant who does not take either part of the course and desires to attend the clinical practice of the hospital must pay a fee of 5 guineas for each three months of attendance. To enable postgraduates to obtain special experience in this branch of medicine clinical assistants are appointed from time to time. Further particulars may be obtained from the Physician-Superintendent, Monks Orchard, Eden Park, Beckenham, Kent.

NATIONAL HOSPITAL, QUEEN SQUARE

Special courses for the Diploma in Psychological Medicine are not held at the National Hospital, Queen Square, London, W.C.1, but lectures are given which cover all the work necessary for the more organic side of the examination—namely, anatomy, physiology, and pathology of the nervous system and clinical neurology.

THE TAVISTOCK CLINIC

The course of training arranged by the Tavistock Clinic, Malet Place, London, W.C.1 (formerly the Institute of Medical Psychology), covers the whole field of the psychoneuroses. For the purposes of the University of London postgraduate diploma in psychological medicine, it provides facilities for the practice in psychoneuroses and early psychoses and in mental retardation and delinquency required under Regulation 3, Section 2 (*d*) and (*e*), for this diploma.

Postgraduate courses of lectures in psychotherapeutic theory and method are given. These consist of a five weeks introductory course of lectures with case discussions, and a systematic course of lectures, given twice a week throughout the year, which may be attended by any qualified medical practitioner. The year's clinical course is arranged for those who wish to practise psychotherapy, and are prepared to give a minimum of twelve hours a week (attending on three days). The course is limited to a membership of twelve practitioners. The full course of the Clinic, designed for those who wish to specialize in psychotherapy, is a two-year course, application for the second year's course being made by those who have completed the year's clinical course.

A course of ten lectures for general practitioners on "The Neuroses in General Practice" will be given on Thursday evenings beginning early in October, while Professor Jung will give five seminars in April, 1938.

THE INSTITUTE OF PSYCHO-ANALYSIS

The course of training arranged by the Institute of Psycho-Analysis (London Clinic of Psycho-Analysis), 96, Gloucester Place, W.1, offers medical students and practitioners the opportunity of acquiring such knowledge of psycho-analysis as will qualify them to practise it. The curriculum extends over a minimum of four years.

The Public Health Medical Services

The Ministry of Health for England and Wales is a central authority to secure the adoption and effective administration of measures conducive to the health of the people, and to promote research work and the proper training of persons for health services.

For the purpose of local public health administration the whole of England and Wales is divided into counties, county boroughs, boroughs, and urban and rural sanitary districts. The administrative County of London, exclusive of the City of London, is divided into twenty-eight metropolitan boroughs.

The public health medical services for Great Britain embrace between three and four thousand medical men and women who give whole-time services; and, in addition, a large number who give part-time services. Less than one-half of the medical officers of health of England and Wales are whole-time officials; but it is certain that their number will be considerably increased in the future, for the Ministry of Health is favourable to whole-time services, and certain provisions of the Local Government Act of 1929 will assist in this connexion. Medical officers for these services are appointed by the Ministry of Health for England, and the Boards of Health for Scotland and Wales; and by the many local public health authorities.

The Medical Services of the Central Authority

The medical work of the Ministry of Health has been organized under the control of a Chief Medical Officer. It is subdivided into seven sections, with a senior

medical officer at the head of each. About a hundred and twenty medical officers are employed, of whom rather more than one-half are regional and deputy regional medical officers employed for certain duties under the Health Insurance Acts. Briefly, the sections deal with environmental hygiene, epidemiology, and international health; maternity and child welfare; tuberculosis and venereal diseases; the supervision of the food supplies; sanitary administration in relation to infectious diseases; national health insurance; and the school medical service. Vacancies in the staff are advertised from time to time in the medical journals, and appointments are made by the Minister on the recommendations of a Selection Committee. These are Civil Service appointments, subject to the usual conditions as to pension, holidays, etc. Medical officers are also employed for similar services by the Welsh Board of Health (Cardiff) and the Department of Health for Scotland (Edinburgh).

The Medical Services of the Local Authorities

These appointments include: medical officers of health, tuberculosis medical officers, maternity and child welfare medical officers, venereal diseases medical officers, and school medical officers—who work in the health interests of the school child. By the larger local public health authorities assistant medical officers are also appointed, and these posts often serve as stepping-stones to the higher offices as vacancies, which are required to be advertised, occur.

Medical Officers of Health

The duties of the medical officer of health are: to inform himself upon all influences affecting, or threatening to affect, injuriously the public health within his district; to advise his sanitary authority upon all matters relating to health; and to perform all the duties imposed upon him by statutes, by-laws, and regulations. He must prepare and submit to his local authority special and annual reports; give immediate information to the Ministry of Health of any serious outbreak of disease, and forward weekly returns of notified cases of infectious disease. Subject to the instruction of his sanitary authority, he must direct or superintend the work of sanitary inspection.

Under regulations made in 1935 no person is qualified to be hereafter appointed or reappointed as a medical officer of health of any district or combination of districts unless, in addition to the qualifications prescribed by any statute, he is also either registered in the *Medical Register* as the holder of a Diploma in Public Health, Sanitary Science, or State Medicine. The appointment of a medical officer of health is made subject to the approval of the Minister of Health.

The Public Health (Officers) Act, 1921, which was promoted by the British Medical Association, provides that a whole-time medical officer of health of a county borough or urban and rural district in England and Wales, a part of whose salary is contributed by the Exchequer, shall not be appointed for a limited period, and shall not be removed from his office except by or with the consent of the Minister of Health.

Under the Sanitary Officers Order, 1926, a medical officer of health who does *not* devote his whole time to the duties of his office, but a portion of whose salary is obtained from Exchequer grant, may be appointed without any limit of time; in which case he cannot be removed from office without the consent of the Minister. If he is appointed for a specified term, say one year, he continues to hold office from year to year unless the Minister consents to his removal. Where the electing body pays the whole of the salary of such a medical officer of health he may be dismissed from office without reference to the Minister of Health. Therefore there is now security of tenure for the posts filled by the large majority of medical officers of health.

A considerable number of authorities have now adopted the Local Government and Other Officers Superannuation Act, 1922. Under this Act, if an officer is incapacitated by ill-health after ten years of service, or if he has reached 65 years of age, he is entitled to superannuation. Such superannuation is to be on the following scale: after ten years' service, 10/60 of the average salary which he received during the last five years of employment; after eleven years, 11/60; and so on up to a maximum of 40/60 after forty years of service. This Act, however, remains permissive, and it fails to make due allowance, in computing service for purposes of superannuation, for the more advanced age, as compared with other officials, at which the medical officer of health can enter the public service. In these two respects the position reached falls short of that for which the British Medical Association has been working for some years. Apparently the Government feels that the time has come when such a provision should be made general in its application; and a Bill before Parliament in June, 1937, aimed at making superannuation compulsory upon all local sanitary authorities.

In Scotland the position is different in some respects. Under the Public Health (Scotland) Act, 1897, no one can be appointed as medical officer of health for any area unless he possesses the Diploma in Public Health. No medical officer can be removed from office except with the sanction of the Board of Health. A "proper" salary must be paid, and the local authority may not bring about the resignation of the officer by indirect means, such as reducing the salary or attaching new conditions to the appointment. The Act says nothing about superannuation or the age of retirement.

School Medical Officers

School medical officers are appointed by local education authorities. Primarily their duty is to detect among the children attending the public elementary schools any physical or mental defect which may retard education, and to inform the parents of its existence. Most approved schemes of medical inspection include arrangements which facilitate the task of parents in obtaining for their children the necessary treatment, check the results of this treatment, and keep each defective child under skilled observation both at home and at school until it has passed altogether out of the education authorities' hands. Indeed, it is now the practice for the education authorities themselves to provide for certain ameliorative work, notably the prescription of glasses where necessary, dental treatment, the removal of adenoids and tonsils, and treatment in connexion with certain communicable diseases of the skin and some physical and mental defects. The general effect of all schemes alike is to make the inspection imposed by law of benefit, not merely to the individual child, but to the community at large, by preventing the development of conditions which lead to the existence of inefficient citizens among the adult population. The work is so related to that of medical officers of health that, generally, the senior school medical officer fills both appointments, his work, when necessary, being supplemented by that of whole- or part-time assistants. A diploma in public health is almost always required of those entering the school medical service of local education authorities.

In Scotland, while the statutory authority for the work of the school medical service is different, the scheme of work is broadly the same.

Tuberculosis Medical Officers

A tuberculosis medical officer is an officer with special training and experience in tuberculosis work, and of a suitable age and attainments to command general confidence. In England such officers are appointed by county councils and county borough councils, and their duties are to carry out the work of diagnosis of tuberculosis, to advise as to treatment, and to take charge of the work of tuberculosis dispensaries and sanatoria where these are in operation. The work under tuberculosis schemes is co-ordinated with the general public health work of local authorities, and so the medical officer of health is often appointed as the chief tuberculosis officer even when a special tuberculosis officer is on the staff of the local authority. The arrangements in Scotland are very similar. In Wales tuberculosis work is carried out under the aegis of the Welsh National Memorial Association, upon which the constituent local authorities are represented, and the powers of appointment of tuberculosis officers are vested in the Association.

Maternity and Child Welfare Medical Officers

Any local public health authority, however small, may make arrangements for maternity and child welfare work within its area, although very generally the smaller local authorities are provided for in county council schemes; but the Minister of Health may transfer the administration of the maternity and child welfare work of an area to the local education authority where this would conduce to more efficiency. For the schemes of the smaller local authorities the services of a part-time medical officer are obtained when the medical officer of health does not himself undertake the duties; but for the larger schemes special whole-time appointments are made. The maternity and child welfare medical officer is responsible for the work at the centres provided and for directing the home visitations; and these activities are closely co-ordinated with the other branches of public health work directed by the medical officer of health.

Much of this work was commenced in different parts of the country by voluntary organizations; some of it still remains in their hands, but is now fairly closely linked up with the public health local authority; and the tendency is for the whole of it to be undertaken by the local authorities. A large number of women medical officers have been appointed to these posts.

Venereal Diseases Officers

Schemes for the diagnosis and treatment of venereal diseases are provided and administered by county councils and county borough councils. In some cases the officer is on the whole-time public health staff, and in others he is a part-time official. Special knowledge and practical experience in the treatment of venereal diseases are required. The officer appointed for either whole-time or part-time service works at one or more clinics, and also gives instruction and assistance in the treatment of venereal diseases to general practitioners, who, if they desire to obtain experience, are allowed to attend the clinics.

Remuneration in the Public Health Service

In order to ensure that public health authorities may obtain skilled and highly trained medical officers it is essential that such officers should receive salaries commensurate with their attainments, bearing a reasonable relationship to the time and money expended in fitting them for their important and responsible duties, and comparing well with the income which might be secured in other lines of medical work. With this end in view the British Medical Association and the Society of Medical Officers of Health prepared a scale of minimum commencing salaries for whole-time public health medical officers.

The scale, which was put into operation in 1925, was attended with a large measure of success. There were, however, certain aspects of it which were not entirely satisfactory. For instance, it was not retrospective, and did not, therefore, apply to medical officers who had been appointed prior to the date on which it came into force, and it contained no provision for specified increments in salary.

As the result of a series of conferences between representatives of the various Associations of Local Authorities, the British Medical Association, and Society of Medical Officers of Health, under the chairmanship of Lord Askwith, a "Memorandum of Recommendations" in regard to salaries of public health medical officers was drawn up and came into force in June, 1930. This Memorandum was published in our *Supplement* on July 27, 1929. Copies of the Memorandum may be obtained from the Medical Secretary of the Association. It has been adopted by the Representative Body, and has been accepted by the representatives of the following bodies representing local authorities:

The Association of Municipal Corporations.
The Urban District Councils Association.
The Rural District Councils Association.
The London County Council.
The Association of Education Committees.
The Mental Hospitals Association.
The Metropolitan Boroughs Standing Joint Committee.

Practically all the local authorities of England and Wales are now applying this Memorandum. The advertisements of local authorities who are not prepared to put into effect the whole of the Recommendations are not accepted by the *British Medical Journal*, which in this matter has the co-operation of the *Lancet* and the *Medical Officer*.

The great advantage of the Memorandum is that it embodies a general agreement as to salaries and conditions of service, and is not merely a scale of salaries. It is retrospective, and will therefore benefit officers appointed before it came into force. It provides stated increments for practically all medical officials except whole-time chief, deputy, and chief assistant medical officers of health, who, as chief medical officials, may, it is presumed, depend that the commencing salaries mentioned in the agreement will be increased for meritorious work and years of service; and it contains a very valuable provision by which questions of difficulty can be referred to an advisory committee.

The British Medical Association represents the profession on the advisory committee, putting the point of view of the public health officers in the discussion of the cases of those who are receiving remuneration less than that laid down in the scale.

For the right class of practitioner with leanings in the direction of public health work the service offers an attractive career, but it must be recognized that there are comparatively few posts which carry high salaries.

Curriculum for the Diploma in Public Health

The existing Regulations and Rules of the General Medical Council for Diplomas or Degrees in Public Health came into force on October 1, 1931.

The curriculum must extend over a period of not less than twelve calendar months (or an academic year of whole-time study covering a period of not less than nine calendar months) subsequent to the attainment of a registrable qualification.

Every candidate for Part I of the examination for the D.P.H. must produce evidence of having attended, during

not less than 280 hours, at an institution approved by the licensing body granting the diploma, practical instruction in:

(*a*) Bacteriology and parasitology (including immunology, serology, medical entomology, etc.), especially in their relation to diseases of man, and to those diseases of the lower animals which are transmissible to man;

(*b*) Chemistry, physics, radiology, and electrology in relation to public health;

(*c*) Physiology and biochemistry in their application to nutrition and hygiene;

(*d*) Meteorology and climatology in relation to public health.

Every candidate for Part II must produce evidence of having received, during not less than 120 hours, at an approved institution, instruction in the following subjects:

(*a*) The principles of public health and sanitation;

(*b*) Epidemiology and vital statistics;

(*c*) Sanitary law and administration (including public medical services);

(*d*) Sanitary construction and planning.

Every such candidate must also have attended for three months on the clinical practice of a recognized hospital for infectious diseases, and have received therein instruction in the methods of administration. At least twenty-four daily attendances of not less than two hours each are required.

Every candidate for Part II must also produce evidence that he has, during a period of not less than six months, been engaged in acquiring a practical knowledge of the duties of public health administration under the supervision of a medical officer of health, who must certify that the candidate has received, during not less than three hours on each of sixty working days, practical instruction in these duties, and also those relating to:

(*a*) Maternity and child welfare service;

(*b*) Health service for children of school age;

(*c*) Venereal diseases service;

(*d*) Tuberculosis service;

(*e*) Industrial hygiene;

(*f*) Inspection and control of food, including meat and milk.

(Instruction in (*a*) to (*f*) must include attendance at the centres, clinics, institutions, and premises concerned.)

Certificates of having received this prescribed instruction in public health administration can be given only by a medical officer of health who devotes his whole time to public health work; or by the medical officer of health of a sanitary area having a population of not less than 50,000; or in Ireland by the medical superintendent officer of health of a county or county borough having a population of not less than 50,000.

The General Medical Council has judged it desirable to add the following note to their Resolutions and Rules:

The observance of these rules does not prevent any licensing body granting the degree or diploma, or an institution approved by such body from requiring a larger number of hours than those specified to be spent in the study of prescribed subjects, or requiring instruction to have been given in subjects additional to those prescribed. Indeed, the use in the rules of the word "include" implies that knowledge of other subjects may possibly be tested as part of the examination. The duties of local government authorities and their medical officers are constantly being extended by the legislature, and modern scientific research is making available in several new directions knowledge of the greatest importance to medical officers of health and to other medical officers engaged in public health work. These factors emphasize the value to medical officers of a knowledge of such subjects as hospital provision, equipment, and administration; of mental disorder and deficiency; and of genetics—all in their relationship to public health; and these subjects may well become part of the curriculum of public health instruction.

In May of this year (1937) the General Medical Council adopted some alterations in the Rules, and these are to come into operation on October 1, 1938. After this date a candidate for the D.P.H. will no longer be required to hold a *registrable* qualification in medicine: nor need two years elapse between the date of obtaining his medical qualification and his entry to the final examination for the D.P.H. Thus a student will be able to proceed directly after his medical qualification to the course of training for the D.P.H., and at the conclusion of this he may sit for the examination: but he will not be granted the diploma until two years from the date of his qualification. Therefore the D.P.H. will be regarded as a postgraduate diploma, the necessity for those of the public health service to hold a *registrable* qualification being secured by the Local Government Act, 1933.

As to the training courses, it will be required that not less than three consecutive calendar months shall be devoted to whole-time study. Practical instruction will be required only in bacteriology and parasitology (including immunology, serology, and medical entomology, in relation to the public health). The examination will not require practical laboratory work in any other subjects. So instruction in chemistry, physics, physiology, and biochemistry need not include laboratory exercises by students, although doubtless these will be provided at most schools.

Examination for the Diploma in Public Health

The examination for the D.P.H. is divided into two parts, and no candidate is allowed to sit for the final part until after an interval of two years from the date of his obtaining a registrable medical qualification. The object of this two years' interval is "to provide opportunity for candidates, while passing from the state of pupilage to that of responsible practice, to give mature consideration to the obligations and duties involved in the work of the Public Health Service, and to acquire direct experience of medical work in a responsible capacity, in general medical practice, in hospital or laboratory appointments, or in any special branch of clinical work or study related to State Medicine."

Any candidate who possesses a qualification entitling him to registration on the British, Dominion, or Foreign List of the *Medical Register* can be admitted to examination, provided he has complied with the regulations of a licensing body in the United Kingdom based on the rules of the General Medical Council, and that before being admitted to Part II of the examination his qualification has been registered in the United Kingdom.

The examination for Part I embraces practical, written, and oral tests in the subjects set out in the Regulations of the curriculum relating to that part; and the same is true of the examination for Part II. A candidate must pass in all the subjects of Part I before being admitted to the examination for Part II.

Only diplomas in public health granted by approved bodies in the United Kingdom are registrable in the *Medical Register*.

Training and Examining Centres for Public Health Qualifications

Degrees in Sanitary Science are conferred, in England, by the Universities of London, Durham, Liverpool, and Birmingham: in Scotland, by the Universities of Glasgow and Edinburgh; and in the Irish Free State, by the National University of Ireland. In most cases these degrees are conferred only upon medical graduates of the universities granting them.

Whereas the requirements of the General Medical Council for the Diploma of Public Health are strictly conformed to, these requirements are extended, as a rule, as to both the period and the scope of special studies demanded, before Degrees in Sanitary Science are granted.

Most universities in Great Britain and Ireland grant a D.P.H. and provide for the necessary training. The English and Scottish Conjoint Boards and the Irish

Colleges also grant these diplomas. The School of Physic of Trinity College, Dublin, was the first body in the British Isles to arrange for courses of instruction and for a Diploma in Public Health. At Cambridge the teaching and training courses for the D.P.H. were terminated at the end of 1931.

In London the postgraduate teaching and training in public health is provided mainly at one centre—the London School of Hygiene and Tropical Medicine (University of London); the only other training centre which offers such facilities is the Royal Institute of Public Health, Queen Square, Bloomsbury, W.C.1.

The course of study for the D.P.H., as provided by the London School of Hygiene and Tropical Medicine (Keppel Street, Gower Street, London, W.C.1), which is a School of the University of London, covers a period of nine calendar months in the case of whole-time students, and is so designed that students can proceed to the academic diploma of the University of London. The course of study provided in the School is intended primarily for those who can devote the whole of their time to the work. A uniform date of entry is essential in a course of this nature, and students must commence work at the beginning of the autumn term. The session opens on September 28 and closes at the end of the following June. Examinations in Parts I and II of the Academic Diploma in Public Health of the University of London are held twice yearly—Part I in January and June, and Part II in July and September. Students who possess a medical qualification which is not registrable with the General Medical Council may be permitted to enter for the examination for the Academic Diploma in Public Health, and a special School Certificate in Public Health will be awarded to all such students who satisfy the examiners. The School undertakes research work in preventive medicine, and members of the public health services have a common room placed at their disposal, and are invited to attend staff and special lectures.

The University of Liverpool grants a Diploma in Public Health to medical practitioners eligible under the rules drawn up by the General Medical Council. The course of study for the diploma extends over a period of not less than twelve calendar months (or an academic year of whole-time study covering a period of not less than nine calendar months) subsequent to the attainment of a registrable qualification. The examinations for Part I are held annually in March and June, and for Part II in June and October. On the recommendation of the examiners, the diploma may be awarded with a mark of distinction in the case of candidates who reach a required standard. All particulars regarding courses of study, examinations, and fees can be obtained on application to the Dean of the Faculty of Medicine.

The University of Manchester has a well-equipped department of bacteriology and preventive medicine, where candidates preparing for the examinations of the various university and examining boards for the Diploma in Public Health can obtain instruction. It also prepares candidates for the Diploma in Bacteriology granted by the university. Full particulars can be obtained from the Dean of the Medical School, the University, Manchester.

The University of Wales grants a Diploma in Public Health under conditions which comply with the requirements of the General Medical Council. Examinations are held twice yearly for Part I in June and October, and for Part II in October (immediately after the examination for Part I in that month) and in January. Candidates must hold a registrable qualification and have taken the courses of study for the diploma at the Welsh National School of Medicine, a constituent School of the University. The courses commence in October and continue throughout the succeeding twelve calendar months. They are so arranged as to permit of part-time study. The Institute of Preventive Medicine, situated in Cardiff, is equipped with laboratories for teaching and research in public health, and a library is provided for the use of students. The Public Health Departments of the City of Cardiff and the County of Glamorgan, and the Joint Public Health Laboratories provided by these authorities and accommodated at the institute, form the centres of practical instruction, their medical officers of health, bacteriologists, and chemists being lecturers in the department of preventive medicine of the School. In the public health departments of Cardiff and Glamorgan a limited number of salaried half-time posts, tenable for one year only, are open to medical men or women who intend to study for the diploma in the Welsh National School of Medicine. Applications for such appointments must be made to the respective medical officers of health. Further particulars may be obtained from the Secretary, Welsh National School of Medicine, 10, The Parade, Cardiff.

The University of Edinburgh grants a Diploma in Public Health. The course, which extends over an academical year of nine months' full-time study, can be commenced in October only, and provision is made by the university for instruction in all the subjects. Candidates for the diploma must be graduates in medicine and surgery of the University of Edinburgh, or must hold corresponding degrees or registrable medical qualifications, which must be registered before a candidate is admitted to the second examination. The course for the diploma is divided into two parts, for each of which examinations are held twice annually. In each part the candidate must pass in all the specified subjects at one examination.

The University of Glasgow confers the B.Sc.(P.H.) and the D.P.H., and conducts complete qualifying courses for both at its Institute of Hygiene and, for administrative work, in the Public Health Department of the city. The course for the diploma is divided into two parts, and admission to the examination is contingent upon the candidate having complied with the following conditions, which apply also to the Edinburgh D.P.H.:

PART I.—(*a*) Completion, subsequent to obtaining a registrable medical qualification, of the course of instruction prescribed for Part I.

PART II.—(*b*) Completion, subject to obtaining a registrable qualification of the course of instruction prescribed for Part II; (*c*) a lapse of two years after obtaining a registrable qualification; (*d*) previous passing of examination in all subjects of Part I.

The Royal Naval Medical College and the Royal Army Medical College provide courses of training to the medical officers of these two Services.

Degrees and Diplomas in Public Health are registrable qualifications, but not so those in Tropical Medicine and Hygiene.

Qualifications in Tropical Medicine and Hygiene

The University of London grants a degree (M.D. in Tropical Medicine) to its medical graduates. A course of training is normally required, extending over at least one academic year.

Diplomas in Tropical Medicine and Hygiene are granted, in England, by the University of Liverpool and by the English Conjoint Board; and, in Scotland, by the University of Edinburgh. Among the institutions which provide qualifying courses are the London School of Hygiene and Tropical Medicine, the Liverpool School of Tropical Medicine, and the Royal Army Medical College. In the last-mentioned institution the training provided is restricted to Army medical officers. The training period for these diplomas is about six months. Graduates of medicine and surgery of recognized universities whose degrees are not registrable in this country may enter for the examination of the English Conjoint Board, and the conditions of study may be modified on the grounds of previous work in the Tropics or of original investigations undertaken.

Facilities for research work are provided at each of the above-mentioned centres for training.

The Colonial Office has decreed that the holder of a D.T.M. and H., or of a D.T.H., is eligible for appointment as a medical officer of health in places and districts other than those with large populations. In the latter cases a D.P.H. is required.

The Services

ROYAL NAVAL MEDICAL SERVICE

The Royal Naval Medical Service offers to well-qualified medical men a satisfactory career, with good opportunities for the practice of their profession and for specialization in many subjects, good pay, and the prospects of promo-

tion to the higher ranks, with an adequate pension on retirement.

Entrance is on a short-service basis for an initial period of three years, to be extended to five years at the discretion of the Admiralty. Officers leaving the Service at the end of three years are eligible for a gratuity of £400, while those who leave at the end of five years receive £1,000.

On appointment, new entrants undergo an initial course, during which they receive instruction in the naval aspects of medicine and the organization and administration of the Naval Medical Service. This is followed by a period of service at one of the principal naval barracks or hospital, and is succeeded by various periods of service at home or abroad, afloat or ashore, as required.

General medical and specialist courses of duration varying from three to six months are arranged, and this postgraduate instruction is supplemented by the promotion course referred to under Promotion below.

Officers may be transferred to the Permanent List at the discretion of the Admiralty during the year in which they attain four years' seniority as surgeon lieutenant. A gratuity of £1,000 (less income tax) is paid, but the officer is required to render a minimum of twenty-five years' service in order to qualify for full pension, including seniority granted, if any, in respect of civil hospital time. With regard to the latter, ante-date of seniority of not more than one year may be allowed in respect of whole-time or resident appointments in civil hospitals held prior to entry to the Royal Naval Medical Service. The ante-date counts for seniority and eligibility for increase of pay, and if the officer is transferred to the Permanent List it counts also as service for the purposes of promotion and retired pay, or gratuity on retirement.

Opportunities are afforded for officers to specialize during the course of their career, and the number of specialist posts carrying additional emoluments is over eighty-five.

Candidates should preferably be between the ages of 24 and 28.

PAY AND ALLOWANCES

(Full Pay—Current Rates)

	Per annum
	£ £
Surgeon Lieutenant (short service and permanent service)	438 *to* 478
Surgeon Lieutenant Commander (promoted after 6 years' service)	578 to 611
Surgeon Commander (promoted after a further 6 years' service)	742 to 1,058½
Surgeon Captain (promoted by selection)	1,074 to 1,320
Surgeon Rear-Admiral (promoted by selection)	1,734
Medical Director-General	2,262½

An outfit allowance of £50 towards cost of uniform is given.

	Per diem
Allowance when in charge of hospitals and sick quarters	10s. and 5s.
Specialist allowance	5s.
Allowance to Senior Medical Officer in flag ship	5s. and 2s. 6d.

PROMOTION

Promotion to surgeon lieutenant commander is automatic, subject to the necessary minimum of sea-time being served and to satisfactory reports. Promotion to surgeon commander is principally governed by success at a promotion examination, prior to which a course of five months' postgraduate instruction is given. In the higher ranks promotion is strictly by selection. The total number of surgeon captains and officers above that rank is forty. Every permanent officer becomes eligible for selection for a higher post after eight years' service as surgeon commander, and promotion usually takes place after eleven to twelve years' service in that rank.

Provision allowance and lodging allowance are paid when victualling and accommodation are not provided.

The extra allowances alluded to in this table are not to be looked upon as very exceptional. About a quarter of the medical officers of the Navy are drawing extra allowances.

PENSIONS

Naval officers retire at certain ages according to the rank they have attained. Except for those promoted to the forty higher posts, the usual retiring age is 55 as surgeon commander, the appropriate pension according to scale being £543 per annum.

The current scale of pensions is as follows:

	Maximum Retired Pay
Surgeon Vice-Admiral	£1,082 per annum on vacating office
„ Rear-Admiral	£914½ per annum at age of 60
„ Captain	£814½ „ „ 57
„ Commander	£543 „ „ 55
„ Lieutenant Commander and Surgeon Lieutenant	£107½ „ 45

Officers permitted to withdraw receive gratuities on the following scale:

Over 10 and under 15 years' service	£500
„ 15 „ 18 „ „	£1,800
„ 18 years' service	£2,700

Applications.—No examination for entry is held, but candidates will be required to present themselves before a Selection Board of the Admiralty, presided over by the Medical Director-General of the Navy, Admiralty, London, to whom application should be made for further details.

General.—The cost of living in a Naval mess, afloat or ashore, is very moderate, and does not, as a general rule, exceed £10 a month.

ROYAL ARMY MEDICAL CORPS

The Royal Army Medical Corps offers to well-qualified medical men a satisfactory career, with good opportunities for the practice of their profession and specialization in many subjects, good pay, and prospects of promotion to the higher ranks with an adequate pension on retirement.

The appointment of officers to the R.A.M.C. is, in the first instance, by means of a short-service commission for a period of five years.

In the fourth year of service an officer is given the choice of retiring with a gratuity of £1,000 at the end of five years' service or of applying for a permanent commission in either the Royal Army Medical Corps or the Indian Medical Service. In the reorganized service, introduced as a result of the recommendation of the Warren Fisher Committee, the prospect of promotion to the higher ranks necessarily depends upon a rigid control of entry into the permanent service. It is not possible on this account to say exactly what proportion of officers who now enter the Corps will be eligible for permanent commissions, but in all probability about 50 per cent. will have the opportunity of doing so. Those retiring with a gratuity after five years' service are liable to be called up for duty in the event of a national emergency arising during the twelve years following their retirement.

New entrants are commissioned in the rank of lieutenant, and the first three months of their service are on probation, during which time they undergo a course at the Royal Army Medical College, London, in hygiene, tropical medicine, entomology, etc., in addition to their military training at the Royal Army Medical Corps Depot at Aldershot. A grant of £50 is made for the purchase of uniform.

An entrant who is holding, or who is about to hold, at the time of entrance an approved whole-time appointment at a recognized civil hospital may be seconded while holding such appointment up to a maximum period of twelve months. A candidate who has held such an appointment within six months of entry may be granted an ante-date up to twelve months in respect of the period the appointment was held. The period of secondment or ante-date will not reckon in diminution of the period of five years which he is required to serve on a short-service commission, but on completing one year of actual service in the R.A.M.C. the period of secondment or ante-date will count for seniority. If appointed to a permanent commission the period of secondment or ante-date counts as service for promotion to the rank of major, increases

of pay in the ranks of captain and major, and retirement on retired pay or with gratuity.

Promotion

Promotion to captain is after one year's commissioned service on full pay. If appointed to a permanent commission promotion to the rank of major is on completion of ten years' commissioned service. Promotion to the ranks of lieutenant-colonel and colonel is by selection to fill vacancies within the establishment, which is designed to allow promotion to those ranks on the average after seventeen and twenty-five years' service respectively.

Professional Opportunity

The possibilities for good work are very great. There is scope for original research in tropical diseases, in preventive medicine, and in bacteriology, as well as in the large clinical field open to the specialist in medicine, surgery, gynaecology, diseases of the ear, nose, and throat, ophthalmology, and venereal diseases. Child welfare is also undertaken systematically by officers of the R.A.M.C.

Young officers having special qualifications or experience in particular branches of medicine or surgery can, if found sufficiently expert, be graded as "Physician," "Otologist," "Gynaecologist," etc. They would then be eligible to fill specialist appointments.

Foreign Service

The tour of foreign service in India, Burma, and Egypt is five years, in Gibraltar and Malta four years, and in other stations three years, but in the case of those officers retiring on a gratuity after five years' service, arrangements would be made for them to return to England at public expense by the end of that period.

Postgraduate Study

A permanent commissioned officer, between his sixth and tenth year of service, undergoes a course of postgraduate study at the Royal Army Medical College and the London hospitals of five months' duration, followed by a course of study of a special subject selected by himself, provided he has shown special aptitude in the postgraduate course or during his previous service. During this course of study he remains on full pay, and the fees for the course are paid by the State. When qualified in his special subject the officer, up to and including the rank of lieutenant-colonel, becomes entitled to specialist pay at 4s. 6d. per day when holding a specialist appointment.

Pay and Allowances: Retired Pay, etc.

The present rates of pay and allowances and retired pay are given in the following tables. In addition, an officer at home below the rank of colonel in charge of a hospital of fifty beds or more receives charge pay at the rate of 5s. a day. There are also available specialist appointments which carry with them an additional rate of pay of 4s. 6d. a day.

Rank	Pay (per annum) approx.	Allowances (Home Rates) approx.	
		Married	Single
	£	£	£
Lieutenant	362	198	134
Captain	447	236	134
Captain after 6 years' service	496	236	134
Captain after 8 years' service	535	236	134
Major	621	239	173
Major after 13 years' service	703	239	173
Major after 16 years' service	742	239	173
Major after 18 years' service	827	239	173
Major after 22 years' service	891	239	173
Lieutenant-Colonel	949	240	201
Lieutenant-Colonel after 3 years' service as such	1,031	240	201
Colonel	1,156	275	227
Major-General	1,570	434	383

Pay in India is appreciably higher than that at home.

General.—The pay of officers even in the lowest rank is ample to enable them to be independent, and the expenses of R.A.M.C. messes are kept under strict supervision so that all tendency to extravagance may be checked and junior officers prevented from finding difficulty in living on their pay.

Retired pay consists of two parts: (*a*) a service element based on the officer's total service; (*b*) a rank element for the substantive rank from which the officer retires. An officer with less than twenty complete years' service will not be eligible for retired pay on voluntary retirement.

The following are the maximum current rates of retired pay:

Rank	Yearly Rate of Retired Pay	Compulsory Retiring Age
	£	
Major	407.5	55
Lieutenant-Colonel	543	55
Colonel	724	57
Major-General	905	60
Lieutenant-General	1,086	60 (or on completion of tenure)

Gratuities

A short-service officer not appointed to a permanent commission may retire with a gratuity of £1,000 after five years' service as a medical officer. Such an officer is liable, during the twelve years following retirement, to be recalled to service at a time of national emergency. Officers holding permanent commissions, with less than twenty years' service as medical officers, may be permitted to retire with gratuities in accordance with the following scale:

With less than 10 years' service as a medical officer	£1,000
After 10 years' service as a medical officer	£1,500
After 15 years' service as a medical officer	£2,800
After 18 years' service as a medical officer	£3,500

Applications.—Entry takes place twice yearly, at the beginning of May and November. The regulations for admission, giving full details, can be obtained from the Under Secretary of State (A.M.D. 1), War Office, Whitehall, London, S.W.1, and should be carefully studied. A personal interview with a representative of the Director-General, Army Medical Services, is readily obtainable.

MEDICAL BRANCH OF THE ROYAL AIR FORCE

The Air Council attaches great importance to attracting into the service the best type of medical man, since on the capacity of the Medical Branch depends in a peculiar degree the safety and efficiency of the Air Force. The duties of a medical officer in the Air Force include not only the prevention and treatment of those ordinary diseases to which the personnel of any fighting service are liable but the special study of the mental and physical stresses imposed on the airman in diverse circumstances and climates—a new branch of medicine which still provides considerable scope for research.

As promotion to the higher ranks of the Service is by selection, and as a certain proportion of the higher ranks are reserved for purely professional as opposed to administrative appointments, it will be seen that there are excellent prospects for the young medical officer who exhibits ability and energy in his professional work. The work to be done, therefore, has a high professional interest, combined with good rates of pay and allowances, so that a career is offered to those who are selected for permanent commissions which should prove both attractive and interesting. The life is one which is certain to appeal to

the man of wide outlook who desires opportunities for travel, sport, and games, and can find interest and enjoyment in aviation. His duties will, as a matter of course, give him flying experience as a passenger, which is necessary for the proper study of the medical problems of aviation and for gaining first-hand knowledge of the conditions under which his comrades serve. He may also, if he wishes, learn to fly when this can be done without interference with his duties.

COMMISSIONS

The establishment consists partly of permanent and partly of short-service officers, and an officer on entry is granted a short-service commission for a period of three years on the active list (which may be extended to five years) and of four years in the Reserve of Air Force Officers. Selections for permanent commissions are made from officers holding short-service commissions who are considered to be suitable and who desire a life career in the Service. Those who are not selected are transferred to the Reserve at the expiration of their period of service on the active list.

But the short-service commission with its gratuity after three or five years is in itself an attraction to many entrants who desire to enlarge their experience and outlook from the points of view of subsequently entering private practice, and who, on entry, have not made up their minds to the adoption of a permanent career in the Service.

For certain purposes medical officers may be allowed to count as service their time spent in approved whole-time post-graduate appointments in civil hospitals under certain well-defined and generous conditions.

At about five years' service all permanent officers who are judged suitable will be given the opportunity to take a course of specialist study, towards the expense of which an allowance is made. The period allowed will vary with the subject of study, but usually about nine months will be available to each officer, during which full pay and allowances will be issued. Their subsequent career will normally be as follows. Approximately three-quarters of the employment of squadron leaders and senior flight lieutenants is in specialist posts, though these are not generally of a full-time specialist character. On reaching the rank of wing commander the policy is to allow a proportion of officers to become permanent specialists and to be employed continuously throughout the remainder of their career in full-time specialist posts. In addition there are a number of hygiene posts in the rank of wing commander open to specialists in that subject, thus further increasing the proportion of specialist posts open to officers. In the rank of group captain, apart from the posts already mentioned as available for the permanent specialist, employment is nearly equally divided between posts in charge of a large hospital and headquarter administrative posts. This statement indicates the position as regards specialist employment as at present foreseen.

New entrants into the Royal Air Force Medical Branch are commissioned as Flying Officers (Medical), and are eligible for promotion to the rank of Flight Lieutenant (Medical) after one year's service on full pay. Accelerated promotion to the rank of Squadron Leader may be granted at any time after eight years' service to officers qualified to hold specialist appointments; those officers who are not so qualified will be eligible for promotion to this rank after ten years' total service. Promotion within establishment to the ranks of Wing Commander and above is by selection. The number of permanent commissions granted yearly is regulated with a view to all suitable permanent officers being promoted to Wing Commanders and of a substantial proportion of Wing Commanders being promoted to Group Captains.

There is no competitive examination on entry: candidates, who must be under 28 years of age, are interviewed by a Board presided over by the Director of Medical Services, Royal Air Force, before acceptance. Each candidate must produce: 1. Birth certificate. 2. Medical registration certificate. 3. A declaration containing the following information: (*a*) Age and place of birth; (*b*) that he is a British subject, the son of British subjects, and of pure European descent; (*c*) that he is ready to engage for general service at home or abroad as required; (*d*) the qualifications he is possessed of, and what medical or other appointments he has held (if any); (*e*) that he is willing to fly as a passenger whenever called upon to do so.

Each candidate is required, before acceptance, to pass a medical examination to ensure that he labours under no constitutional or mental disease or weakness, or any imperfection or disability which may interfere with the efficient discharge of the duties of a medical officer in any climate, in peace or war.

On appointment entrants undergo an initial course of three months, during which they are given instruction in the special medical aspects of aviation, hygiene and tropical medicine, the organization and administration of the Royal Air Force, and the general and special duties to be performed by officers in the Medical Branch.

UNIFORM AND EQUIPMENT: LEAVE

An allowance of £50 towards the cost of uniform is made on joining to candidates who have not had previous commissioned service in H.M. Forces. Subject to the exigencies of the service, officers at home are allowed ordinary leave up to sixty-one days in a year; officers abroad may accumulate leave up to ninety-one days, which may be taken on return home. Full pay is granted for ordinary and accumulated leave.

EMOLUMENTS

The emoluments of medical officers of the Royal Air Force are given in outline below. The rates of pay are fixed on an inclusive basis, and the fact that specialist pay and charge pay are not payable as separate emoluments was taken into account when the rates were fixed.

In addition to pay officers receive quarters (with fuel and light), rations, and attendance, or, if these are not available in kind, they are given cash allowances in lieu as shown in the table. The rates and general scheme of allowances are subject to review as circumstances may require. Married officers who have attained the age of 30 years receive either married quarters or allowances at the married rates.

Rank	Pay (per annum)	Allowances (per annum) (Present Home Rates)	
		Married	Single
	£	£	£
Flying Officer	395	—	123
Flight Lieutenant	429	234	123
Ditto, after 2 years as such	462	234	123
Ditto, after 4 years as such	496	234	123
Squadron Leader	645	237	162
Ditto, after 2 years as such	709	237	162
Ditto, after 4 years as such	742	237	162
Ditto, after 6 years as such	809	237	162
Wing Commander	909	239	190
Ditto, after 2 years as such	943	239	190
Ditto, after 4 years as such	1,040	239	190
Group Captain	1,156	310	252
Air Commodore	1,320	366	312
Air Vice-Marshal	1,652	430	373

Special allowances are applicable at stations abroad.

RETIRED PAY AND GRATUITIES

The minimum period of service qualifying for retirement on retired pay is twenty years. The maximum rates of retired pay and the compulsory retiring ages for the several ranks are:

Rank	Yearly Rate of Retired Pay	Compulsory Retiring Age
	£ s.	
Air Vice-Marshal	914 10	60
Air Commodore	860 0	59
Group Captain	814 10	57
Wing Commander	543 0	55
Squadron Leader	452 10	55

Officers of the rank of Group Captain and below can normally reach the maximum rate of retired pay of their rank.

A permanent officer allowed to retire before having qualified for retired pay may be granted a gratuity, namely:

After 5 but less than 10 years' commissioned service	£1,000
After 10 but less than 15 years' commissioned service ..	£1,500
With 15 or more than 15 years' commissioned service.. ..	£2,800

Short-service officers who complete their full period of service on the active list will normally be granted gratuity as follows on transfer to the Reserve:

After 3 completed years	£400
After 5 completed years	£1,000

These gratuities will not be repayable to officers granted permanent commissions, but their service on a short-service commission will count towards retired pay.

DISABILITY AWARDS, WIDOWS' PENSIONS, ETC.

Permanent medical officers invalided from the Royal Air Force are eligible for retired pay or gratuity however short their service may have been. If the disability in consequence of which they are invalided is attributable to the conditions of their service and is assessed at 20 per cent. or more, they receive an addition, varying according to the degree of disablement, to the retired pay or gratuity for which they may be eligible. Provision is also made in the regulations for pension to the widow and allowances to children or dependants of a deceased officer.

GENERAL

The pay of officers even in the lowest rank is ample to enable them to be independent, and the expenses of Air Force messes are strictly limited in order to check all tendency to extravagance and to prevent even the most junior officer from finding difficulty in living on his pay. The regulated limit of the daily rate of messing is 5s. and the average rate at present charged at home stations is 3s. 6d. Subscriptions and the cost of mess entertainments are charged according to an officer's rate of pay, and an unmarried officer taking his full share in the life of the mess should not incur a mess bill of more than £10 a month (6s. 8d. a day). This sum would include a wine bill of £1 a month (an actual average figure), but would not include goods, such as tobacco, bought through the mess.

INDIAN MEDICAL SERVICE

The Indian Medical Service offers a permanent career with wide opportunities of medical experience, including clinical, preventive, specialist, and research work. Admission to the Service is by selection and nomination by the Secretary of State for India, and inquiries should be addressed to the Secretary, Military Department, India Office, Whitehall, S.W.1.

Candidates should be under 32 years of age, and must possess a qualification registered in Great Britain and Northern Ireland under the Medical Acts in force, or an Indian medical qualification recognized under Section 11 (i) of the Indian Medical Council Act, 1933, and registered in British India under one of the Provincial Medical Acts. Officers are appointed in the rank of Lieutenant, and are normally promoted to Captain on completion of one year's full pay service.

COMMISSIONS AND APPOINTMENTS

All European officers are appointed to *permanent* commissions, but they may retire voluntarily with a gratuity of £1,000 after six years' service or £2,500 after twelve years' service. In such cases officers are provided with free passages to the United Kingdom.

The Service is primarily a Military Service, but 142 posts under the civil administration are specifically reserved for officers of the Indian Medical Service (Civil). European officers are appointed to 115 of these and are eligible, together with Indians, for appointment to 24 of the remainder. These posts include civil surgeoncies, which provide for the medical needs of civil officers and for general medical administration; specialist appointments as physicians, surgeons, and gynaecologists, etc., at civil hospitals; research posts; and professorships at important medical schools. Officers are not normally eligible for transfer to civil employment until they have done at least one year's service in India. Except in the case of officers who are specially selected for certain appointments, transfers to civil employment are not usually made until the completion of 4 or 5 years' service in India.

RATES OF PAY

Year of Service	Rank	Basic Pay, Rs. per mensem	Overseas Pay, £ per month	Total, £ per annum
1	Lieutenant	450	15	585
2	Captain	500	25	750
3	"	550	25	795
4	"	550	25	795
5	"	600	25	840
6	"	600	30	900
7	"	700	30	990
8	"	700	30	990
9	"	700	35	1,050
10	"	700	35	1,050
11	Major	800	35	1,140
12	"	800	40	1,200
13	"	800	40	1,200
14	"	800	40	1,200
15	"	800	40	1,200
16	"	950	40	1,335
17	"	950	40	1,335
18	"	950	40	1,335
19	"	1,100	40	1,470
20	"	1,100	40	1,470
21	Lieutenant-Colonel	1,350	40	1,695
22	"	1,350	40	1,695
23	"	1,350	40	1,695
24	"	1,500	40	1,830
25	"	1,500	40	1,830

NOTE.—(1) The rupee is at present stabilized at a rate equivalent to 1s. 6d.

(2) An officer promoted to the rank of Lieutenant-Colonel before completion of 20 years' service will receive pay at the rate of Rs. 1,200 per mensem (basic) *plus* £40 per month overseas pay.

(3) Overseas pay is admissible only in the case of officers who, at the date of their appointment to the Indian Medical Service, had their domicile elsewhere than in Asia. All service which counts for increments of basic pay counts also for overseas pay.

In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special rates of pay are also attached to numerous administrative appointments.

ANTE-DATES IN COMMISSION

Candidates possessing certain higher medical qualifications may be granted an ante-date of one year in their commissions, and candidates possessing a D.P.H. receive an ante-date of six months. An officer who has held an approved whole-time appointment in a civil hospital is also eligible for an ante-date equivalent to the period of his appointment but not exceeding one year. Persons holding or about to hold such appointments may be seconded in those posts for a period not exceeding one year. The maximum period of ante-date secondment, or ante-date and secondment combined, is limited to 18 months. An officer granted an ante-date of twelve months is promoted Captain on arrival in India.

OUTFIT ALLOWANCE: PRIVATE PRACTICE

Officers on appointment will receive an allowance of £75 towards the cost of outfit.

With the exception of administrative officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice so long as it does not interfere with their proper duties.

LEAVE

Leave can be taken at reasonable intervals, and adequate rates of leave pay are provided. Extra leave (known as study leave), which may not exceed twelve months in all during an officer's service, may be granted to officers desirous of pursuing special courses of study of a postgraduate nature. During such leave study allowance, at present fixed at the rate of 12s. a day in the United Kingdom, £1 a day on the Continent of Europe, and £1 10s. a day in the United States of America and Canada, is granted to an officer in addition to ordinary rates of leave pay.

PENSIONS

The rates of pension are as follows:

	Per annum £	s
After 17 years' service for pension	372	0
" 18 " " "	400	0
" 19 " " "	428	0
" 20 " " "	465	0
" 21 " " "	502	0
" 22 " " "	539	0
" 23 " " "	576	10
" 24 " " "	614	0
" 25 " " "	651	0
" 26 " " "	697	10
" 27 " " "	744	0

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments as Colonels or Major-Generals. Officers who elect to remain in civil employment after 17 years' service will not be promoted above the rank of Lieutenant-Colonel, but will be eligible for higher pensions.

PASSAGES

An officer on appointment is provided with free passage to India. The families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges. Officers of non-Asiatic domicile and their families are also eligible for passage concessions under which they are granted a certain number of return passages home for themselves and their wives and children at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately three months, prior to their embarkation for India on first appointment. Information as to the rates of pay admissible during this period and subsequently up to arrival in India is contained in the memorandum referred to below.

A detailed memorandum regarding these appointments and forms of application may be obtained from the Under Secretary of State for India, Military Department, India Office, London, S.W.1.

The Army Dental Corps

The corps is administered by the Director-General, Army Medical Services. The regulations for admission to the Army Dental Corps should be obtained from the Under Secretary of State, War Office, and carefully studied.

LOCAL GOVERNMENT HOSPITAL SERVICES

The growth of the municipal or council hospital during the last two years has meant not only greatly extended and modernized hospital provision for the public, but the creation of new medical staffs in the employment of local authorities and also the furnishing of increased teaching facilities of which many medical schools have taken advantage. In London alone, for example, the general and special hospitals of the County Council employ a staff of nearly 400 medical officers and over 250 consultants, and seventeen of the hospitals are linked with the medical schools for teaching purposes.

These hospitals have arisen by a metamorphosis from the old Poor Law infirmaries. Instead of being, as formerly, under the control of boards of guardians and other minor authorities, they are administered by county and county borough councils. No longer are they regarded merely as institutions for the reception of the chronic sick; they have assumed the curative and research functions of the voluntary hospital. Under the more progressive authorities the old institutions have become unrecognizable, with, in the general hospital, new receiving wards, out-patient departments, more and better maternity accommodation, modernized operating theatres and sanitary annexes, the provision and extension of nurses' homes and central kitchens; and, at the special hospitals, isolation blocks, additional accommodation for patients and staff, and various reconstruction and improvement schemes.

The differentiation between the voluntary and the municipal hospital every year becomes less definite, and thus the need becomes greater for their co-operation. By one of the sections of the Local Government Act, 1929, which brought about all this municipal development, the local authority is instructed to consult with the voluntary hospitals and their professional staffs with regard to the extension of hospital accommodation. In some areas this has been done, and the range of subjects for consultation has been enlarged: witness the splendid example of Manchester, where the first Joint Hospitals Advisory Board has been set up. But in many parts of the country the section remains a dead letter. Indeed, only rather more than half the county boroughs, and of course a much smaller proportion of the counties, have so far "appropriated" to general and special hospital purposes the institutions which they inherited from the guardians. Nevertheless the municipal hospital is assuming an important place in the hospital picture. The change in administration has coincided with a change in public sentiment. The institutions which were disliked and dreaded by the poor while they remained Poor Law infirmaries, and were generally disregarded by the medical profession also, have now become popular, and their popularity extends beyond the class of persons they were originally intended to benefit.

The London County Council Services

The London County Council is the largest of the local authorities in respect of the hospital accommodation it controls and the medical staff which it employs. It has set an example by the advantage which it has taken of the Local Government Act. Under that Act it took over a total of seventy-six hospitals and institutions. These included twenty-eight general hospitals, the largest of which is Lambeth, with accommodation for 1,300 patients: eight of the others have accommodation for over 700. The total cost of maintenance of the various hospital services is some four and a half millions a year, of which nearly three millions is spent on the general hospitals. The total bed accommodation in the hospitals and allocated institutions on transfer was 41,164, but this included nearly ten thousand beds in institutions, the majority of which could not be regarded as suitable for the proper treatment of sick persons. A great deal of structural work and readaptation was put in hand, with the result that a net increase of more than 1,400 beds has been provided.

There were admitted to these hospitals a large number of acute cases, both medical and surgical, but there is, of course, this difference between them and the voluntary hospitals, that the latter can select their patients and reject whom they please, whereas the rate-supported institutions must be prepared to admit any sick poor person who applies, provided that, in the opinion of the medical superintendent, such a patient is suitable for admission. Some 37,000 operations were performed in the general hospitals during the last year for which full records were available (1935), and the number of out-patient attendances was more than 554,000. The chronic sick poor are gradually being concentrated in twelve other institutions which, unlike the rest, are for the present, for administrative reasons, not under the Public Health Acts.

So far as maternity and child welfare services are concerned, the City Corporation and the Metropolitan Borough Councils are the responsible authorities, but the London County Council has maternity beds in its general hospitals, and in several hospitals a fully equipped maternity and

gynaecological block. To the maternity wards of the Council's hospitals in 1935 over 15,000 cases were admitted. The accessory medical services under the Council are also important; these include pathological laboratories, x-ray units, and a large ambulance organization. In addition to smaller units, the Council has five pathological laboratories, each of which serves a group of institutions attached to the municipal service. These five are at Lambeth, Highgate, Lewisham, Mile End, and Kensington. Arrangements have been made whereby postgraduate students of the London School of Hygiene and Tropical Medicine may obtain experience of the technical and administrative methods adopted in these laboratories—experience of a kind very difficult to obtain in the ordinary way.

Provincial Hospitals

The same general provisions hold good in various degrees of other progressive cities. The *Hospitals Year Book, 1937*, gives particulars of fifty-five general and children's hospitals in provincial cities administered by the local authorities. The average bed accommodation in these hospitals is over 600; the whole-time medical staff numbers 300, and the part-time staff some 450. Birmingham has under its council four general hospitals, two infectious diseases hospitals, two maternity homes, two babies' hospitals, four convalescent homes, and four sanatoria. The medical staff, whole and part-time, attached to its general hospitals numbers over forty. Newcastle-upon-Tyne, with a hospital accommodating 700, has a staff of twenty-five. Other large provincial towns show comparable figures. Hospitals which remain under the Poor Law also have their whole-time and part-time staff. Edmonton (Middlesex) Poor Law Hospital, for example, has a medical staff of twenty-eight, made up about half of whole-time and half of part-time officers. Smithdown Road, Liverpool, with 1,200 beds, has ten whole-time and eleven part-time officers. In addition to the large general hospitals, maternity and children's hospitals are provided by the larger authorities. In Birmingham, for example, there are thirty maternity and child welfare centres under the control of the Public Health Committee.

In Manchester a great scheme of reorganization of the consultant medical and surgical services has been brought about at the three general hospitals controlled by the city council—namely, Crumpsall (1,438 beds), Withington (1,179), Booth Hall (760). The first two are general hospitals for adults, and the third a general hospital for children. All three were formerly Poor Law establishments. Under the new arrangements, which have been made in order to overcome the previous inadequacy of specialists in number and in the number of their visits, there are or are to be forty-one consultant appointments, with a total of ninety-five attendances per week. The new salary bill will be £12,500 per annum, representing about 50s. per specialist's attendance. Under the joint hospital advisory board for Manchester, already mentioned, it is hoped to co-ordinate the activities of all the hospitals, voluntary and municipal.

Facilities for Instruction

A great amount and variety of clinical material is contained in these hospitals, and many of them are used for undergraduate and postgraduate teaching. In London some useful discussion has taken place between the London County Council and the representatives of the voluntary hospitals. At several of the general hospitals under the old board of guardians arrangements for instruction were made, but these have been much extended since the hospitals came under Council control. Sixteen of the Council's general hospitals have been affiliated to the London voluntary hospital medical schools. Teaching in obstetrics is afforded in seven of the Council's hospitals. Facilities are also afforded at the Council's pathological laboratories to postgraduate students in order that they may obtain experience in technical and administrative methods. As an example of the amount of material which may be afforded by a Council hospital, St. James's, Wandsworth, may be cited, where there is a clinic of fifty beds always occupied with serious fracture cases. It is proposed to set up at St. Mary's Hospital, Carshalton, at a cost of £116,000, a new antitoxin establishment designed and equipped on modern lines.

The postgraduate school at Hammersmith Hospital, the result of a partnership between the Government, the University of London, and the London County Council, was opened in May, 1935, by King George V. So much has been written about this great development that it is hardly necessary to recapitulate here all that it embodies. The new institution has been "recognized" as a school of London University. There are four professorships, three in the main clinical subjects—medicine, surgery, and midwifery and gynaecology—and the fourth in pathology. The school buildings consist mainly of laboratories, lecture theatres, and other accommodation (non-residential), while the associated developments and adaptations of the Hammersmith Hospital adjoining include two new blocks of buildings for the casualty, receiving, and out-patient departments, a new ward, a massage and light treatment section, and other facilities. The County Council has provided at Hammersmith a radiological department which serves as a consultative centre for the whole of the hospital service, where cases can be sent from other hospitals for expert opinion on diagnosis and treatment. Arrangements are being made at this school for postgraduate courses for insurance practitioners under a scheme arranged by the Ministry of Health.

It may be added that the clinical material in municipal hospitals is not only vast in amount, but includes a great deal with which it is very important that the young practitioner should be familiar, and which is not much represented in the teaching hospitals. In a recent report to the L.C.C. it is mentioned that the type of case treated in the general hospitals is altering, and there is a continually increasing amount of acute and operative work to be carried out.

Medical Staffing

The policy pursued by the London County Council and other authorities is to provide a whole-time medical service and to have a permanent staff at each general hospital. The grades of officers are: medical superintendents, deputy medical superintendents, senior assistant medical officers, assistant medical officers, and house-physicians and surgeons (resident), and part-time clinical assistants (non-resident). The medical superintendent is required to be a man of high qualifications in at least one branch of medicine, as well as a good administrator and first-class technician. In addition to the medical superintendent, one or more whole-time medical officers, with special qualifications in medicine, surgery, or obstetrics, are appointed. Preference is given to officers holding the higher medical qualifications, M.R.C.P. or M.D. in the case of physicians, F.R.C.S. or M.S. in the case of surgeons. These are graded as senior assistants, and at the larger hospitals one of them ranks as deputy medical superintendent. Deputy medical superintendents are employed as a rule only at hospitals with over 600 beds, of which there are sixteen among the London County Council general hospitals. These officers at institutions with over 750 beds are described as of Grade I, while those at hospitals of from 600 to 750 beds are of Grade II. Senior assistant medical officers are also graded according to the size of the hospital they serve. The appointment to these posts is made to qualified medical practitioners of at least one year's standing in their profession who have held a residential post for at least six months in a general hospital. Those who seek assis-

tant medical officerships at the special hospitals will find general hospital experience desirable, although the lack of it does not debar otherwise suitable candidates. The engagements of assistant medical officers of Grade I are limited to four years, terminable at any time by a month's notice on either side, and the first year of service is on probation. Should the officer's name be on the promotion list at the end of his four-years term, he may remain beyond the period of the original engagement, and at an increased salary. Assistant medical officers of Grade II are on a yearly engagement, but this has been found unsatisfactory to the Council, because of the need for frequent appointments, and because officers leave at a time when, having learnt the ways of the hospitals, they are most useful. It is proposed to renew such appointments for a second year. The junior appointments are those of resident house-physicians and surgeons and part-time clinical assistants. These officers consist of recently qualified men and women who are appointed for limited periods, generally six months, and need not have had previous hospital experience. The six-months period may be extended for further similar periods up to a maximum of two years, provided that not more than twelve months is spent in one hospital.

Scale of Salaries

Medical superintendents in London receive as a maximum between £900 and £1,650 per annum, including an unfurnished house or quarters, valued at £100 a year for superannuation purposes, and the rates on which are paid by the Council. The salary scales are:

General Hospitals	£900 to £1,550
Convalescent Hospitals..	£900 to £1,100
Fever Hospitals	£900 to £1,450
Tuberculosis Institutions	£900 to £1,200
Children's Hospitals	£950 to £1,650

Of the general hospitals only two of the smallest in the London County Council area have a commencing salary of £900; at the other end of the scale two have commencing salaries of £1,300. One condition made is that the appointment is to the Council's hospital service, not to an individual hospital, and appointment to the service includes liability, if called upon, to take part in consultations or perform operations at another hospital, although if this happens frequently, on account of the special skill or experience of the officer concerned, a claim for extra remuneration may be considered. Further, in addition to their ordinary remuneration as medical superintendents, the chief medical officers of the infectious hospitals service and of the children's institutions and surgical tuberculosis service receive an allowance at the rate of £200 a year, and the chief medical officer of the medical tuberculosis service, who is also a medical superintendent at a hospital, an additional allowance at the rate of £125.

The scale of salaries for other officers, subject to certain modifications in the different hospitals, is as follows:

Medical Appointments	Remuneration.*		
	Minimum	Increase	Maximum
	£	£	£
Deputy medical superintendent (Grade I)..	650	50	800
" " " (Grade II)..	600	30	750
Senior assistant medical officers (Grade I)	550	25	650
" " " (Grade II)	500	25	600
Assistant medical officers	350	25	425
" " " (yearly engagement)	250	—	—
House-physicians and house-surgeons ..	£120 (resident)		
Clinical assistants (non-resident)	£150 (non-resident) and no emoluments, but meals when on duty		

* Exclusive of the emoluments of board, lodging, and washing, valued at £150 per annum in each case.

In the country generally medical superintendents of Poor Law infirmaries are paid from £600 a year upwards to £1,600, with emoluments; deputy medical superintendents, from £450 to £750, with similar emoluments, and resident assistant medical officers, from £200 to £450, with full board.

Residence, Leave, and Pensions

Generally speaking, all assistant medical officers in London are required to be resident. If in any case the question of an assistant medical officer being non-resident should arise, the primary consideration is the interests of the service. Lately the London County Council, in order to enable male members of its senior staff to marry and remain in the Council's service, has made alternative scales of salary for staff provided only with unfurnished quarters as distinct from board, lodging, and laundry. The scales are: deputy medical superintendents, Grade I, £700—£50—£850 a year; Grade II, £650—£30—£800; senior assistant medical officers, Grade I, £600—£25—£700; Grade II, £550—£25—£650. Non-resident medical officers who are receiving the allowances in lieu of residential emoluments pay for any meals taken at the hospital. Permission to live out is granted only if the accommodation is required or can be utilized for some other purpose.

Liberal annual leave, with pay, and sick leave, with pay, for a reasonable period are allowed by the L.C.C. Leave is also granted for study purposes, not only to officers who are following a university course, but to those who are undertaking other courses of study or research work. The house-physicians and surgeons are not regarded as employed in a whole-time capacity, and reasonable off-duty periods for study are allowed. Clinical assistants attend six sessions of four hours' duration each week. Assistant medical officers also are allowed six weeks in any one year may be granted, not exceeding in accordance with the service of with rates of pay varying to improve their qualifications, and leave of absence the officer. Occasional daily leave for attending a course of instruction for a medical degree or diploma is granted with full pay. These concessions, however, are subject to the condition that the officer shall continue for a certain period in the service of the Council.

Whole-time permanent appointments are pensionable under the Council's superannuation and provident scheme, which provides for a pension and lump sum payment after the necessary qualifying period of service. Pensions are also payable to officers on the fund who break down in health after not less than ten years' service. Officers resigning have their contributions returned to them, and death benefit is also paid in respect of officers of five years' service or more. Marriage is no longer a bar to the employment of full-time women doctors by the Council, but a difficulty arises in resident appointments, owing to the lack of married quarters, and therefore all women members of the hospital medical staff, including the mental hospital service, are excluded from the scope of the concession, with the exception of part-time consultants and specialists.

Consultant and Specialist Services

Under the new scheme, which came into operation in 1933, the general hospitals have been divided into seven groups on a geographical basis, and the special hospitals and public assistance institutions in the area linked up with them, so that consultants and specialists, who were previously engaged chiefly for individual hospitals, whether at annual salaries or at a fixed charge for visits, are now appointed to the service and utilized as required for the groups of hospitals. The salaries for the part-time consultants and specialists are generally £125 a year for one session a week, and £75 a year for each additional session, a session to be approximately of 2½ hours' duration. Full-time consulting physicians and surgeons receive £1,250 a year, rising by increments of £50 to £1,500 a year, with no emoluments. The full-time radiologists receive £900 a year, rising by increments of £50 to £1,100. Consulting urologists are paid on a visit basis—two and a half guineas per visit. The appointment of part-time consultants and specialists is subject to annual review.

Method of Entrance to the Service

Many provincial areas have now highly developed schemes providing for the employment of many medical

men and women of high qualifications at salaries of from £450 to £800 per annum, and, in addition, large numbers of junior officers at salaries of from £200 upwards are employed. These posts offer to all grades remarkable facilities, which should appeal to those who desire to gain experience and at the same time wish to adopt for a period the institutional life. It is a service in which the original appointment and any subsequent promotion depend upon merit, and in which vacancies in the higher grades are filled so far as possible from the existing staff, with no barrier preventing transference from one grade to a higher. Vacancies are usually advertised in the medical journals.

The opportunities of the Local Government Hospital Service to those whose career will be spent in general or consultant practice, as well as to those who expect to spend their lives in the public health service, scarcely need to be stressed. One point which the final-year student or the newly qualified practitioner will do well to bear in mind is that some authorities in offering appointments insist upon candidates possessing previous resident hospital experience. Such a requirement may not arise for some years, but the medical man or woman who has gone direct to serve as locumtenent or assistant may find himself or herself cut off from certain avenues of work through having neglected to take resident experience immediately after qualification. We are informed that it is almost the rule for the young medical woman to take a residential post, but the young medical man often forgoes this experience. It is certainly deplorable that a competent man should, through ignorance on qualification, deprive himself of the opportunity of following his bent in later years.

It has to be borne in mind, however, that the attractiveness and opportunity of a post under the new public assistance authorities, notwithstanding the effect of the Act of 1929 in assimilating the Poor Law to other public health services, are affected not a little by the policy adopted by the local authority concerned. In the more progressive areas there is a high degree of differentiation in treatment between the sick and mentally afflicted on the one hand, and the purely pauper class on the other—that is to say, between the hospital and the public assistance institution, formerly called the workhouse. The tendency in such areas has been to develop the hospital services on lines approximating to those obtaining in the voluntary hospitals.

In addition to the hospital appointments of the character mentioned, the Local Government Service offers numerous other (part-time) posts, such as those of public assistance medical officer and public vaccinator, which are commonly held by private practitioners. Domiciliary work in the public assistance medical service has been found, as the result of a recent inquiry, to be in many areas very inadequately recompensed, and in localities where unemployment is rife and increasing numbers of people are resorting to public assistance the work is becoming more onerous. An assurance has been given by the Ministry of Health that where such increase of work is definitely proven, the local authority will be encouraged by the Ministry to listen to the plea for an increase of remuneration.

Enough has been said to show what variety of service, whole-time and part-time, institutional and domiciliary, the Local Government Service offers, on the one hand, to the ambitious who desire experience, and, on the other hand, to those who seek a secure position, with superannuation at the end.

PRISON MEDICAL SERVICE

Appointments to the prison medical staff are made by the Secretary of State for Home Affairs on the recommendation of the Prison Commissioners. Application for such appointments should be made on a special form, which can be obtained from the Secretary, Prison Commission, Home Office, London, S.W.1.

In the smaller prisons the post is usually a part-time one held by a local practitioner, but in the larger prisons the members of the medical staff are required to devote their whole time to the service. In the case of those required to give their whole time to the service the appointments are in the first instance as medical officers Class II, and from the seniors of this rank the medical officers Class I are selected as vacancies occur.

Largely as a result of action taken by the British Medical Association the salaries and conditions of prison medical officers have been improved, and now are: Medical officer Class II, £525, rising by annual increments of £25 to £800 (with an allowance of £50 p.a. within the scale to holders of the diploma of psychological medicine); medical officer Class I, £800, rising by annual increments of £30 to £1,000. Unfurnished quarters are provided, or an allowance in lieu is made.

There are 18 medical officers Class II, 12 medical officers Class I, and 26 part-time medical officers. The service is a small one, and therefore vacancies are comparatively rare and the rate of promotion varies. The work offers exceptional opportunities for research in criminal psychology, forensic psychiatry, and mental deficiency.

MEDICAL PRACTICE IN BRITISH DOMINIONS AND FOREIGN COUNTRIES

Medical Acts have now been passed in almost all places forming part of the British Empire beyond the seas, and registers of duly qualified practitioners are consequently maintained. To these registers medical men educated in the United Kingdom are generally admissible merely on payment of a registration fee, providing they produce evidence that they are of good repute and are either registered or eligible for registration in the United Kingdom, as the local requirement may be. The only exception to this statement that need be made relates to the Dominion of Canada. Each of its provinces acts in medical matters as an independent State. The result has been that reciprocity of practice has in the past been established between this country and each of the provinces of Canada except British Columbia, where certain obstacles were never overcome. It has, however, to be recorded that reciprocity no longer exists with Saskatchewan, New Brunswick, Ontario, and Quebec. We would advise any medical man proposing to practise in Canada first to communicate with the Provincial Registrar, stating what degrees or diplomas he holds, and asking for information as to the precise steps he must take in order to obtain admission to the Provincial Register. The Licence of the Dominion Council, which can only be obtained after examination, entitles its holder to registration in any of the provinces of Canada, though in regard to Quebec there is a proviso that "he must have been registered in the province five years prior to the application for the recognition of the Dominion Licence." In order to sit for the examination for the Dominion Licence it is necessary to obtain either a licence from one of the provinces (this can be obtained from one of those with whom reciprocity has been established), or a certificate from a Provincial Council that the requirements of that Council in regard to preliminary education, matriculation, medical curriculum, and graduation have been complied with.

Italy and Japan are the only two foreign States with which complete medical reciprocity has been established, though there are other countries which grant a limited recognition to British qualifications. Generally speaking, in Continental countries (with the exception of the kingdom of Italy) a British medical man desiring to exercise his profession therein must pass practically the

same examinations as those imposed on natives of the country. In France naturalization is now required also. The same observation applies to all foreign States in the South American continent. Each of the United States of North America has its own laws and regulations governing medical practice; and all of them require the holder of a British qualification to submit to an examination. A number of the States, including New York, Illinois, Michigan, and Indiana, require naturalization.

The Chinese National Health Administration has issued a notice, for guidance of foreign medical practitioners, to the effect that they should obtain licences to practise from the Administration, and their bonâ fides must be guaranteed by their consular authorities; they should learn Chinese, and should apply to the Permanent Chinese Delegation of the League of Nations at Geneva before setting out for China.

THE COLONIAL MEDICAL SERVICE

The Colonial Medical Service consists of the Medical Services in Bahamas, Barbados, Bermuda, British Guiana, British Honduras, Ceylon, Cyprus, Falkland Islands, Fiji, Gambia, Gibraltar, Gold Coast, Hong Kong, Jamaica, Kenya, Leeward Islands, Malaya, Mauritius, Nigeria, Northern Rhodesia, Nyasaland, Palestine, St. Helena, Seychelles, Sierra Leone, Somaliland, Tanganyika, Trinidad, Uganda, Western Pacific (Gilbert and Ellice Islands, and British Solomon Islands), Windward Islands, and Zanzibar.

New entrants to the Service will be liable to transfer to any scheduled post therein whether or not such transfer represents promotion, provided that:

(*a*) No officer whose first appointment is to an office in a Dependency in which he was ordinarily resident at the time of appointment shall be liable to be transferred to an office outside that Dependency unless and until he shall have accepted an office in another Dependency.

(*b*) No officer shall be transferred without his own consent to an office which in the opinion of the Secretary of State is of less value (due regard being had to climate and other circumstances) than that which he already holds.

Officers who do not hold scheduled posts are eligible to apply for transfer to such posts. Appointment, confirmation, promotion, retirement, and transfer of medical officers will be governed by the directions of the Secretary of State.

No officer of the Service is entitled, as of right, to private practice, the service being envisaged as essentially a Service of whole-time officials whose primary duty is to the State.

The possession of a qualification registrable by the General Medical Council is a condition of eligibility for admission to the Colonial Medical Service.

Medical appointments in the self-governing Dominions and the territories under their control, and in Southern Rhodesia, are made by the Governments concerned, and are not in general open to candidates in the United Kingdom. In the Bahamas, Barbados, Bermuda, Ceylon, Jamaica, and Mauritius vacancies are practically always filled by the appointment of qualified local candidates or, in the case of some of the higher posts, by transfer from other colonies. Appointments to the medical services of the remaining colonies and other territories under the administrative direction of the Colonial Office are made by the Secretary of State for the Colonies in this country.

Conditions of service and superannuation are in the main determined by the economic resources and general public health policy of the individual colony and its local government, and vary almost as widely as do conditions of climate. Moreover, the extent of the control exercised by the Colonial Office varies according to the constitutional status of the particular colony, and the detailed information available centrally is not always complete. The intending candidate, therefore, should make comprehensive inquiries as to local conditions, and particularly as to facilities for private practice where this is not precluded by the terms of appointment. He will also do well to supplement official information by reference to the Medical Secretary at the Central Office of the British Medical Association (Tavistock Square, London, W.C.1), where reports obtained from time to time from the local Branches are available.

To those physically and mentally suited to the climatic and social conditions peculiar to the various colonies the Colonial Medical Service should, and in most cases does, offer a field of professional activity rich in interest and in opportunity for pioneer work, with increasing facilities for specialization and research.

In a few colonies economical and financial stringency still compels the Administration to continue to modify the terms and conditions of salary and to impose temporary deductions from salaries and allowances, and candidates for appointments should make careful and sufficient inquiry concerning the position in the branches of the Service in which they are interested. In this article the unreduced emoluments, allowances, etc., are quoted. Apart from these temporary disadvantages, however, the outlook for the Colonial Medical Service is in the main a hopeful one, and especially so in the larger and better organized branches.

The medical services recruited in this country by the Secretary of State for the Colonies include those of West Africa, East Africa, Malaya, Hong Hong, the West Indies, Fiji and the Western Pacific territories, and Palestine, besides a number of smaller services offering individually one or two appointments.

In Fiji, although the basic salary of district medical officers (£500, by £25 to £725) is below the £600 minimum recommended as adequate by the British Medical Association, this fact is offset by the concession of allowances of from £175 to £235 in some of the districts where the post of Medical Officer is combined with that of District Commissioner, the value of private practice in the other districts being estimated at from £100 to £600 a year.

The services in the West Indies and some of the smaller colonies have not yet conceded the £600 minimum commencing salary, and whilst facilities for remunerative private practice, general conditions of service, and a relatively low cost of living must in some instances be taken into consideration, these compensations are by no means universal. The service in the Leeward Islands is in a condition which requires special notice by way of warning. The position in Grenada has been improved, though such improvements have not extended to St. Lucia and St. Vincent.

In general, candidates for the Colonial Medical Service must be under 35 years of age. Appointments are, subject to a varying period of probation, for the most part classed as permanent and pensionable, but there are some appointments by agreement for a specified limited term of service. There is no entrance examination, but practitioners selected for appointment must obtain a certificate of physical fitness from one of the consulting physicians to the Colonial Office. Postgraduate experience in hospital appointments is desirable. Successful candidates are normally required to undergo an approved course of instruction in tropical medicine, the fees for their tuition being defrayed by the Government and an allowance being paid during their instruction.

Some sixty medical women are employed in child welfare, maternity, and laboratory work, mainly in the larger services—for example, those in East and West Africa and Malaya. Salaries are the same as for men.

The bulk of the appointments made by the Secretary of State in this country are to East and West Africa and Malaya.

West Africa

The West African Branch of the Colonial Medical Service includes Nigeria, the Gold Coast, Sierra Leone, and the Gambia. Climatic conditions vary considerably over this area, but they are in general admittedly trying. This fact is at present recognized by the provision of more frequent leave periods than are usual elsewhere.

The service includes medical, public health, and laboratory divisions, and specialist posts are almost invariably filled by promotion from the staff. The rate of pay for a medical officer is £660 on appointment for three years; then, on confirmation, £690 a year, rising by annual increments of £30 to £840; then, subject to passing an efficiency bar, £880 a year, rising by annual increments of £90 to £1,000 a year. There are a considerable number of specialist and administrative posts carrying relatively high salaries, varying from £1,200 to £2,000. All appointments in the staff are pensionable. The age at which officers may be called upon to retire compulsorily is 50, and retention in the Service after the age of 55 will require the Secretary of State's approval, which will only be given in exceptional circumstances. Pensions are calculated at the rate of 1/600 of the officer's pensionable emoluments (salary and house allowance) in respect of each complete month of service. The pension will be converted into a reduced pension of three-quarters of the full pension, with a gratuity of ten times the amount of the reduction. Gratuities of £1,000 or £1,250 may be drawn on retirement after nine or twelve years' service. Members of the Service in West Africa are not usually permitted to take their wives or young children with them until they have acquired experience of the conditions of life and have obtained the sanction of the Governor. In the case of young children this is only exceptionally given.

African Medical Officers

A number of Government appointments for African medical officers exist in the West African Colonies. These appointments carry salary on the scale £500-£25-£600, and there are higher scales of £600-£30-£720.

East Africa

This branch of the Service includes Kenya, Uganda, Tanganyika Territory, Northern Rhodesia, Nyasaland, Zanzibar, and British Somaliland. In East Africa there is a very wide scope for clinical work, both medical and surgical, as well as for research and for preventive medicine and sanitation. In most stations conditions allow a medical officer's wife to accompany him, but this is not generally desirable on first appointment. In some Dependencies the consent of the Governor must be obtained. The service includes a medical and a sanitary division. The former is open to those holding ordinary medical and surgical qualifications, postgraduate experience in a hospital appointment being an advantage; posts in the sanitary division will as far as possible be filled by those holding a Diploma in Public Health. Climatic conditions vary considerably. In a considerable part of Kenya they approximate more to the temperate than to the tropical zone; but there are some areas in the East African Dependencies where conditions more closely resemble those in West Africa. The rate of pay for a medical officer is from £600 on appointment, rising by annual increments of £30 to £840, and thereafter, subject to an efficiency bar at this point, by £40 to £920.

The gratuities available on retirement after nine or twelve years' service are similar to those in West Africa, except in the case of officers serving in Northern Rhodesia. Officers may retire on pension on reaching the age of 55 years. Pensions are calculated at the rate of 1/600 of emoluments (including value of free quarters) for each completed month of service. The officer of twenty-five years' service who has reached the maximum of the long scale receives a pension of approximately £520 per annum. Pensions are convertible, under certain conditions, into a reduced pension and a gratuity.

Malaya

This branch of the Service covers the Straits Settlements, the Federated Malay States, and the Unfederated Malay States. The salary of $500 a month, with an annual increment of $25, rising to $800 at the top of the time-scale ($ is fixed at 2s. 4d.), is generally considered adequate in view of the present cost of living, which is somewhat higher than that in England. The officer of twenty-five years' service, even if he has not held a senior appointment carrying a salary above the maximum of the time-scale, receives a pension of approximately £560 per annum. Pensions are convertible under certain conditions into a reduced pension and gratuity.

The climate of Malaya is, for the Tropics, a healthy one. It varies little throughout the year. The average rainfall is about 100 inches a year, and vegetation is always green. People who live regular active lives have no difficulty in keeping in good health. European children do well in Malaya up to the age of about 6.

The professional duties of a medical officer may include medical, surgical, medico-legal, and public health work. His administrative work comprises hospital administration, diets, returns, and financial work, and includes the inspection of smaller hospitals and dispensaries. Districts vary in size, and a certain amount of travelling is necessary. The white population in each district varies. The district hospitals hold from 50 to 300 beds. There is a staff of locally recruited men, mostly trained at the Singapore College of Medicine. Asiatic dressers and trained hospital assistants are employed in hospitals and dispensaries. In addition to European sisters, there is a local nursing staff. All hospital equipment is supplied by Government, including instruments. At both the Institute for Medical Research in Kuala Lumpur, Federated Malay States, and the King Edward VII College of Medicine, Singapore, there are opportunities for research as well as for routine investigations. In addition to the full-time professional posts at the College of Medicine several of the medical staff in Singapore hold part-time lectureships.

Sudan Medical Service

This Service is responsible for carrying out civil medical work and public health duties in the Sudan, and for the health of the Sudan Defence Force.

The climate varies, but is not in general unfavourable, though hot. The northern desert zone is hot and dry in the summer, but with cool nights. In the winter the climate is pleasant and is often cold. The central Sudan for eight months in the year has much the same climate as the northern zone, but there is a rainy season of four months (more or less), during which time there is a considerable rainfall, and large areas become malarious, but in which it is possible to keep limited areas malaria-free. The southern area becomes increasingly tropical in character as the southern boundary of the Sudan is approached. In this area the mosquito-protected house and the mosquito net have to be relied on for the greater part of the year.

The staff consists of (*a*) a director; (*b*) three assistant directors (hygiene and public health; hospitals; laboratory services); (*c*) a senior physician and a senior surgeon to the Khartum Civil Hospital; (*d*) a Government gynaecologist and obstetrician and a Government ophthalmo-

logist; (*e*) a medical officer of health, Khartum Province; (*f*) a number of (at present thirty-two) British "senior medical inspectors" and "medical inspectors," whose pay commences at £720 and rises, subject to the recommendation of the director, by five biennial increases to £1,080, and after thirteen years' service to £1,200. The senior medical inspectors are eligible, by selection, for the senior posts. All medical inspectors are appointed, in the first place, on probation for two years, and if at the end of that time they are accepted for permanent service under the Sudan Government the first increase of pay is subject to their passing an examination in Arabic.

In addition to the above there are (*g*) a number of Sudanese medical officers trained at the School of Medicine at Khartum. There are (*h*) several Sudanese assistant medical officers, who have been given a purely practical training in one of the larger hospitals in the Sudan.

Among the attractions of the service are: the great variety of the work met with among many different races of the Sudan; leave of ninety days, generally granted every year after the first eighteen months of service; study leave, which may be given for some definite purpose. The terms of the Pension and Provident Fund are detailed in the pamphlet on "Information for Candidates" of the Sudan Medical Service, and should be studied in the original. Private practice is allowed but is limited to a few of the larger towns, and may be carried on so long as it does not interfere in any way with official duties. These duties include acting as consultant to the principal hospitals and the supervision of medical and public health work, the inspection of schools, the examination of candidates for Government service and pension, and the training of assistant medical officers and Sudanese sanitary officers and overseers. The Khartum medical school is staffed mainly by members of the medical service, who receive additional remuneration for their work as teachers. A registrar of the medical school is also selected from the service, who receives £250 a year extra pay.

Inquiries for further information should be made to the deans of the principal medical schools, and to Dr. V. S. Hodson, M.V.O., F.R.C.P., 69, Harley Street, W.

Official Sources of Information

All inquiries in connexion with medical appointments in the self-governing Dominions and their Dependencies should be addressed to the High Commissioners or Agents-General for the Dominions. Intending applicants are also recommended to consult the Dominions Office and Colonial Office List, which may be seen at the Colonial Office Library or at the Library of the British Medical Association if not otherwise available, and the Professional Handbook, Part III (price 4d.), issued by the Oversea Settlement Department, Dominions Office, Caxton House, Tothill Street, London, S.W.1.

Inquiries as to vacancies and conditions in the Sudan Medical Service should be addressed in the first instance to Dr. Hodson, 69, Harley Street, London, W.1.

All inquiries in connexion with Colonial medical appointments made by the Secretary of State for the Colonies, or such vacancies as may occur in Palestine, should be addressed to the Director of Recruitment (Colonial Service), Colonial Office, 2, Richmond Terrace, Whitehall, London, S.W.1.

There remain a number of medical appointments made by mining companies and other commercial undertakings in various parts of the Tropics. Much caution should be exercised in accepting such posts, and the form of contract should be subjected to very careful scrutiny. Advice in this connexion should always be sought from the Secretary of the British Medical Association, British Medical Association House, Tavistock Square, London, W.C.1.

SPECIAL DIPLOMAS

Information about the regulations for the various Diplomas in Tropical Medicine, in Psychological Medicine, and in Public Health is given in the appropriate sections of this Educational Number at pages 488–92 and 494. Further details in regard to the D.P.H. and the D.T.M. will be found in the late Sir Andrew Balfour's *Guide to the Regulations, Courses, and Examinations for Qualifications in Public Health and Tropical Medicine*, published by the British Medical Association, Tavistock Square, W.C.1, at the price of 3s.

It should perhaps be noted here that of the various diplomas in special subjects granted by licensing bodies only those in Public Health and Sanitary Science and State Medicine are at present admissible for entry in the official *Medical Register*, though other special diplomas may, of course, be included among the particulars of qualifications set out in the *Medical Directory*.

As stated at page 456 a Diploma in Tuberculous Diseases is granted by the University of Wales to qualified medical practitioners; new regulations for this diploma are now in force.

Diplomas in Medical Radiology

Diplomas in Medical Radiology are granted by the Universities of Cambridge, Edinburgh, Liverpool, and London.

The Cambridge Diploma.—A Diploma in Medical Radiology and Electrology is granted by the University of Cambridge. The primary object is to provide adequate training in a branch of medical work which is becoming increasingly important and difficult, and which is outside the ordinary medical curriculum. Before admission to any course for the diploma a candidate shall produce evidence that he holds a medical qualification approved by the committee and also satisfy the committee that he has had sufficient postgraduate clinical experience. The next course, which begins on October 4, 1937, occupies nine months. The first four months, which can be spent either in Cambridge or in London, are occupied with (*a*) lectures and practical work in physics, in preparation for the examination for Part I in February, (*b*) an introductory course of clinical instruction in radiology and electrology, (*c*) a course of instruction in pathology in relation to radiology and electrology. The next three months must be spent in London, and are occupied with (*a*) lectures and demonstrations in radiology and electrology (including radium therapy) at the British Institute of Radiology, (*b*) clinical instruction in the radiological department of a hospital approved by the committee. During the final two months of the course a candidate must hold a clinical clerkship or similar appointment in the radiological department of a hospital approved by the committee. This part of the course may be done in London or elsewhere. The examination for Part II will be held in July.

Further particulars as to courses and examinations may be obtained from G. Stead, M.A., Secretary for the Diploma, Cavendish Laboratory, Cambridge, or the General Secretary, British Institute of Radiology, 32, Welbeck Street, W.1. Completed application forms must be sent to the Secretary for the Diploma at Cambridge by September 15. Cambridge University has decided to discontinue the granting of the Diploma after 1941. The last course will begin in October, 1940.

The Edinburgh Diploma.—Candidates for the diploma must be graduates in medicine and surgery of the University of Edinburgh, or hold corresponding degrees or qualifications registrable with the General Medical Council of Great Britain, or of such other Universities or Medical Schools as may be recognized for the purpose by the University Court. Candidates are not admitted to the examination for the diploma until after the lapse of not less than one year from obtaining a registrable qualification. The course of study begins in October and extends over a period of not less than three terms. The examination, which is written, oral, and practical, is in two parts: (*a*) physics, and (*b*) radiology. The examination is held twice yearly. Full particulars may be obtained from the Dean of the Faculty of Medicine. In this connexion it may be noted that radiology can now be taken as the special subject in the examination for Membership of the Royal College of Physicians of Edinburgh. Several candidates have already taken radiology

as their special subject; it means that an honours standard has to be attained.

The University of Liverpool grants a Diploma in Medical Radiology and Electrology. Candidates before admission to the examination for the diploma must possess a registrable qualification approved by the university in medicine and surgery, and must have attended courses of instruction in (*a*) physics (two terms); (*b*) (i) radiology and (ii) electrology, during the nine months in the *x*-ray and electrotherapeutic departments of a hospital or hospitals. An examination is held in March and June in physics, in June radiology and electrology. Examination in either part may be taken separately. Fees: tuition, £31 10s.; examination and diploma, £6 5s. An enrolment deposit fee of £5 5s. is charged on application and credited to the fees, but is not returnable in the event of the candidate failing to enrol. These courses commence during the first week in October. Application should be made to the Dean, Faculty of Medicine, the University of Liverpool.

Conjoint Diploma in Medical Radiology (D.M.R., R.C.P.S.).—The examination is divided into two parts, the first comprising physics as applied to radiology, the second medical radiology, with special reference to its clinical application, including radio-diagnosis, *x*-ray therapy, and radium therapy. Both parts will be held in January and July of each year. Candidates may enter for them either together or separately, subject to the production of the required certificates. The course for the diploma extends over one academic year (nine months) of full-time study subsequent to the attainment of a recognized medical qualification. At the discretion of the committee of management the conditions of admission may be modified in special cases, but exemption will not be granted from any part of the examination. A syllabus has been drawn up for Part I of the examination, but not for Part II. The fee for admission or readmission to each part is six guineas. Copies of the regulations may be obtained from the secretary at the Examination Hall, 8–11, Queen Square, W.C.1.

The London Diploma.—The University grants an Academic Postgraduate Diploma in Medical Radiology. The course is open to registered medical practitioners and graduates in medicine of this or another approved university. Students are required to attend a course of study approved by the University, and extending over not less than one academic year, at one or more of the Colleges or Schools of the University. The subjects of the course are as follows: Part I: physics and electrotechnology. Part II: (*a*) radiography and radio-diagnosis; (*b*) radiotherapy. The examination for the Diploma consists of two parts. Candidates may enter for Part I and Part II at the same examination, or may enter for Part I only. The examination will consist of a paper, a practical examination, and an oral examination in each of the subjects under Part I and Part II. Full particulars may be obtained from the Academic Registrar, University of London, W.C.1.

Diploma in Laryngology and Otology

The Conjoint Examining Board in England (Examination Hall, Queen Square, London, W.C.1) grants a Diploma in Laryngology and Otology (D.L.O.) after an examination held in June and December.

The examination comprises two parts: Part I, on the anatomy, embryology, and physiology of the ear, nose, pharynx, larynx, trachea and bronchi, and oesophagus; Part II, on the recognition and use of special instruments and appliances, and the medicine, surgery, and pathology of these regions. Candidates may enter for Part I at any time after a recognized qualification in medicine, surgery, and midwifery has been obtained. Candidates may enter for Part II on completion of one year of special study of diseases of the ear, nose, pharynx, and larynx, after a recognized qualification has been obtained, provided that Part I has been previously passed, and on production of certain certificates. The conditions of study may be modified at the discretion of the Committee of Management in special cases. The fee for admission or readmission to each part is six guineas.

Diplomas in Ophthalmic Medicine

A special Diploma in Ophthalmic Medicine and Surgery is granted by the University of Oxford and by the Conjoint Examining Board in England.

University of Oxford.—The Diploma in Ophthalmology (D.O.) is granted to registered medical practitioners, and to non-registrable graduates of universities approved by the Board of the Faculty of Medicine, after they have passed an examination, which is held annually in June. This examination is open to candidates who have attended a special two-months course of instruction at Oxford, and who have in addition done a ten-months course of clinical ophthalmology at a recognized hospital or hospitals. Entries for the course should be made through the Dean of the Medical School, University Museum, Oxford, from whom any further information that is necessary may be obtained.

The Conjoint Board.—The Diploma in Ophthalmic Medicine and Surgery (D.O.M.S.) of the Conjoint Examining Board of the Royal College of Physicians of London and Royal College of Surgeons of England is issued after completion of an examination held in two parts—in February and July. The examination is partly written, partly oral, partly clinical or practical. Part I comprises anatomy and embryology of the visual apparatus, physiology of vision, elementary optics; Part II comprises optical defects of the eye, ophthalmic medicine and surgery, pathology with special reference to medical and surgical ophthalmology. Candidates may enter for Part I at any time after a recognized qualification in medicine, surgery, and midwifery has been obtained. Candidates may enter for Part II on completion of one year of special study of ophthalmology after a recognized qualification has been obtained, provided that Part I has been previously passed, and on production of certain certificates. The conditions of study may be modified at the discretion of the Committee of Management in special cases. The fee for admission or readmission to each part is six guineas.

Diplomas in Obstetrics

The Society of Apothecaries of London, as stated on page 458, confers a Mastery of Midwifery, and issues a diploma under this title denoting the possession of specialized knowledge of ante-natal care, midwifery, and infant welfare and the public health aspects of these subjects. This is a postgraduate diploma, and is not registrable under the Medical Acts. The same applies also to the new diploma D.C.O.G., which the British College of Obstetricians and Gynaecologists now issues to registered medical practitioners who have had special postgraduate training and experience in the subject and have satisfied the examiners. (See p. 458.)

Diploma in Child Health

The Conjoint Examining Board in England has issued regulations for its new Diploma in Child Health (D.C.H. R.C.P. and S.Eng.), and copies may be had from the Secretary, Examination Hall, Queen Square, W.C.1.

The examination will be held twice a year, in March and October, and will be written, clinical, and oral; fee six guineas. It will comprise the following subjects, special emphasis being laid on their preventive aspects: (*a*) The anatomy, physiology, and pathology in childhood. (*b*) The development of the child, physical and mental, including speech, with their disorders; physical education in childhood. (*c*) The hygiene and dietetics of infancy and childhood. (*d*) Affections of the newborn. (*e*) Disease in infancy and childhood, medical and surgical. (*f*) The therapeutics of infancy and childhood, including remedial treatment, physical and mental. (*g*) Legislation and public administration in regard to the care of children, including the methods of infant welfare centres and of the school medical service. Certificates of experience in children's diseases at a recognized hospital are required.

Diploma in Anaesthetics

The Conjoint Examining Board in England has also issued regulations for a Diploma in Anaesthetics (D.A. R.C.P. and S.Eng.), and copies may be had from the Secretary, Examination Hall, Queen Square, W.C.1.

The examination, to be held in May and November, will be written and oral, the latter part requiring the candidate to demonstrate his knowledge of the use of various types of anaesthetic apparatus. The fee for examination is six guineas, and the subjects are: (*a*) Human anatomy and physiology considered in relation to anaesthesia. (*b*) The history, theory, and practice of anaesthesia, including inhalation anaesthesia;

intravenous, rectal, and other methods of inducing anaesthesia; local, regional, and spinal anaesthesia in all varieties; (c) Pre-operative anaesthesia in its relationship to disease, investigation, preparation, and medication; the recognition of post-operative complications and their treatment in so far as they are related to anaesthesia. (d) The pharmacology and elementary chemistry of drugs used for, or in association with, anaesthesia. Certificates of experience in the administration of anaesthetics in recognized hospitals are required, though the conditions of study may be modified by the Committee of Management at its discretion. Until May 1, 1938, the diploma may be granted without examination to an anaesthetist on the staff of a general hospital associated with a recognized medical school in the British Empire who has held his appointment for not less than ten years; fee six guineas. Inquiries should be addressed to the Secretary of the Board.

Tuberculous Diseases Diploma

Candidates may be admitted to examination for the Tuberculous Diseases Diploma of the University of Wales after the lapse of not less than two years from the date of obtaining a qualification in medicine, surgery, and midwifery, registrable in Great Britain, or in the Dominions, Colonies, and Dependencies of the British Empire. Every candidate must have held a resident post in a tuberculosis hospital, or at an orthopaedic institution providing not less than 100 tuberculosis beds, or shall satisfy the Faculty of Medicine that he has pursued a special study of tuberculosis equivalent to the above for a period of not less than twelve months. The examination is in two parts. Part I (*a*) written, and (*b*) oral and practical, including the examination of patients, and the recognition of specimens; Part II is a written and practical examination on the epidemiology, pathology, and bacteriology of tuberculosis. Every candidate will be required to satisfy the examiners in both parts in the same examination. The course of instruction commences in January and continues until May each year, when the examinations are held. Further particulars may be obtained from the Secretary, Welsh National School of Medicine, 10, The Parade, Cardiff. A limited number of appointments for part-time assistant tuberculosis physicians are advertised annually in September by the Welsh National Memorial Association, enabling suitably qualified and selected candidates to study for the diploma. Particulars on application to the Secretary, Welsh National Memorial Association, Memorial Offices, Westgate Street, Cardiff.

Diploma in Clinical Pathology

The University of London grants an Academic Postgraduate Diploma in Clinical Pathology. The course of study is open to graduates in medicine of this or another approved university, or registered medical practitioners, whose training has, in the opinion of the university, qualified them for registration as students for the diploma. They are required to pursue an approved course of instruction and training, lasting at least one calendar year, as whole-time workers under the supervision of the head of the pathological department of one of the colleges or schools of the university. The examination is held once a year, in December. Candidates must apply to the Academic Registrar for an entry form and a certificate of course of instruction, to be returned duly filled in and attested, together with the fee of ten guineas, by November 8.

University of Lausanne

M.D. EXAMINATION FOR MEDICAL PRACTITIONERS

It has been possible for a long time to obtain the M.D. degree (not registrable in this country) from one of the State Universities in Switzerland—namely, Berne, Geneva, and Lausanne. In 1930 new regulations came into force in the Faculty of Medicine of the University of Lausanne, the main effect of which is to provide a special M.D. examination for medical practitioners from other countries. Particulars may be obtained from Dr. C. A. H. Franklyn, honorary secretary, Lausanne Medical Graduates, 34, Queensway, Wragby Road, Lincoln (booklet and copy of regulations, post free, 2s. 1½d.).

MEDICAL MISSIONARIES

Missionary societies are in constant need of qualified men and women to fill vacancies as they occur in their hospitals, and also to enable them to take advantage of fresh openings. To those suitably endowed the mission field offers unique opportunities for interesting work, and the development of native medical schools, as training institutions in connexion with some of the larger mission hospitals, affords excellent scope for valuable work to medical men and women who are qualified to teach. It is not usually expected that medical missionaries should take a position such as would otherwise be occupied by an ordained clergyman or minister, but it is essential that they should be prepared to exert their influence in any hospital to which they may be sent, so that a Christian atmosphere may be maintained and the work of evangelization be carried on through the ministry of healing.

As for scientific and other qualifications for the work, medical missionaries, in addition to being physically capable of sustaining a life which makes a great demand upon their strength, should be thoroughly well-trained physicians and surgeons. It is very desirable that they should have held a resident appointment at a general hospital, and have a good knowledge of practical surgery, gynaecology, tropical medicine, and the treatment of eye diseases. Useful information can be obtained from the Secretaries of the various Missionary Societies, or from Wm. C. Bentall, O.B.E., F.R.C.S.Ed., Honorary Secretary, Medical Advisory Board on Medical Missions to the Conference of Missionary Societies in Great Britain and Ireland, Rhosilli, Best Beech Hill, Wadhurst, Sussex, or Edinburgh House, 2, Eaton Gate, London, S.W.1.

Dental Surgery

Until the passing of the Dentists Act, 1921, the profession of dentistry in this country was regulated by enactments corresponding very closely with those relating to the practice of medicine—that is to say, there was no direct prohibition of the act of practice; and the Dentists Act of 1878 gave the same degree of protection to legally qualified and registered dentists as was accorded to registered medical practitioners—namely, the reservation of the use of certain titles. This Act provided also (1) that no person should take or use the name or title of "dentist" (either alone or in combination with any other word or words) or of "dental practitioner," or any other name, title, or description expressed in words or by letters implying that he was specially qualified to practise dentistry, unless he was registered, under a penalty of £20; and (2) that an unregistered person could not recover any fee or charge in respect of any dental operation, attendance, or advice. But, in the case of the practice of medicine by unqualified and unregistered persons, certain deterrent factors came into play—such as the inability to give a death certificate—which did not operate to the same extent in the case of dentistry; hence, unqualified practice was far more prevalent in dentistry than in medicine, and increased after a decision of the House of Lords placing a narrow interpretation upon the words "specially qualified to practise dentistry," by defining the word "qualified" as not referring to competence but to the possession of a recognized diploma.

Dentists Act, 1921

This unsatisfactory position was remedied by the passing into law of the Dentists Act, 1921; its provisions are based largely on the recommendations of a departmental committee appointed in 1917 by the Privy Council "to investigate the extent and gravity of the evils connected with the practice of dentistry and dental surgery by persons not qualified under the Dentists Act." Since November 30, 1922, no person has been permitted by law to practise or hold himself out, whether directly or by implication, as practising or as being prepared to practise dentistry unless he is on the *Dentists Register* kept under the Dentists Act, 1878. The practice of dentistry is defined as including "the performance of any such operation and the giving of any such treatment, advice, or attendance, as is usually performed or given by dentists," and the performing of any operation or the giving of any "treatment, advice, or attendance on or to any person as preparatory to or for the purpose of or in connexion with the fitting, insertion, or fixing of artificial teeth." The maximum penalty incurred by an unregistered practitioner is £100 for each offence. There are, however, certain important exceptions to the requirement of registration. A registered medical practitioner may practise dentistry without being on the *Dentists Register*, though, under the National Health Insurance (Dental Benefit) Regulations, he cannot give dental treatment to insured persons as an additional benefit unless he is registered in the *Dentists Register*. A registered pharmaceutical chemist or chemist and druggist may extract a tooth where the case is urgent and where no doctor or dentist is available, but the operation must be performed without any kind of anaesthetic; and minor dental work may be performed in a public dental service under the personal supervision of a registered dentist, provided it is in accordance with conditions approved by the Minister of Health after consultation with the Dental Board.

Dentistry may be carried on by a corporate body provided that the majority of the directors and all the operating staff are registered dentists, and that no business other than dentistry or only some business ancillary to dentistry is carried on by the company. Companies carrying on the business of dentistry at the present time are permitted to continue to do so with certain restrictions, provided that the name of the company as well as the names of the directors have been entered in a list kept under the Act for that purpose. Every director or manager of a company convicted of an offence under the Act will be held to be guilty of the offence unless he proves that the offence was committed without his knowledge, and the court may, in addition to a fine, order that the name of any director convicted shall be removed from the list of directors aforesaid.

The Dental Board

On the establishment of the Dental Board in 1921 certain powers and duties of the General Medical Council were transferred to it, including the duty of erasing from the *Dentists Register* any entry which has been incorrectly or fraudulently made. An inquiry into the case of a person alleged to be liable to have his name erased from the *Register* is made by the Board, which reports its findings to the General Medical Council, the order directing the erasure being made by the Council. A name erased from the *Register* can only be restored by the Council upon a report made by the Board. An appeal to the High Court may be made by any person aggrieved either by refusal of the Board to register his name or by the removal of his name from the *Register*. The administrative expenses of the Board are defrayed from the registration fees and annual retention fees, but any surplus may be allocated to purposes connected with dental education and research or to any public purposes connected with the profession of dentistry. The offices of the Dental Board are at 44, Hallam Street, London, W.1.

Dental Education and Examination

The preliminary examination in arts is the same for medical and dental students, and the early stages of their education embrace much the same subjects[1]; and, as the dental student is required to obtain a knowledge of the broad principles of medicine and surgery, it is necessary for him to pursue some portion of his studies at a medical school as well as at a special dental school, the latter not undertaking the teaching of these subjects. Registration as a dental student is not in all cases compulsory, though it is to be advised as convenient as affording proof of the date at which professional education began, and it is required by most of the licensing bodies, all of whom insist upon a curriculum covering four academic years.

Degrees and diplomas in dentistry are granted by the Universities of Belfast, Birmingham, Bristol, Dublin, Durham, Leeds, Liverpool, London, Manchester, St. Andrews, Sheffield, and the National University of Ireland, as will be found stated in the articles on these universities. Licences in dentistry entitling the holder to be registered on the *Dentists Register* are granted by the Royal Colleges of Surgeons of England, of Edinburgh, and in Ireland, and by the Royal Faculty of Physicians and Surgeons of Glasgow.

Recognized dental schools are numerous. In London there are those connected with the Royal Dental Hospital, Leicester Square; the National Dental Hospital (now the University College Hospital Dental School), Great Portland Street; Guy's Hospital; King's College Hospital; and the London Hospital. In the provinces there are the Birmingham Dental Hospital; the Royal Infirmary and the General Hospital, Bristol; the Dental Hospital and the Public Dispensary, Leeds; the Dental Hospital, Liverpool; the Dental Hospital, Manchester; the Sutherland School, Newcastle-on-Tyne; the Royal Hospital, Sheffield. In Scotland there are the Dental Hospital, Dundee; the Incorporated Dental Hospital and School, Edinburgh; and the Incorporated Dental Hospital, Glasgow; and in Ireland, the Belfast Dental School, the Incorporated Dental Hospital of Ireland, Dublin, and the Royal College of Surgeons in Ireland, Dublin.

All who think of becoming dentists may be advised to study a memorandum, drawn up for their guidance on behalf of the Board, setting out in convenient form and in simple language information for which the Board is often asked.[2] It will be seen from this pamphlet that in order to assist suitable students the Board has instituted a system of bursaries in aid of the payment of fees. Bursaries are limited in amount to £30 a year (subject to exceptions in favour of candidates who are sons of dentists or have received so much previous training in dental mechanics as to be entitled to a reduction of a year in the length of their curriculum).

General Medical Council's Recommendations

The Dentists Act still leaves to the General Medical Council the duty of controlling the course of study and examinations required for dental qualifications.

Revised recommendations as to the course of study and examinations to be required of candidates for degrees or licences in dentistry or dental surgery were adopted by the Council in 1933, and came into force on October 2 in that year. We print them below in a somewhat abridged form.

PRELIMINARY EXAMINATION AND REGISTRATION

Every dental student should, at the beginning of his studentship, be registered in the manner and under the conditions prescribed for medical students. Before registration in the *Dental Students' Register* every applicant should be required to have passed, in addition to the examination in

[1] See the Memorandum on Students' Registration printed in the article on the General Medical Council at page 448.

[2] *Memorandum on the Procedure to be Adopted by Those who Desire to Enter the Profession of Dentistry, with Notes on Costs and Prospects.* 1936. Dental Board of the United Kingdom, 44, Hallam Street, W.1. (Price 1s., post free.)

general education, which shall be the same as that required for medical students, an examination in elementary physics and chemistry, conducted or recognized by one of the licensing bodies, which shall also be the same as that required for medical students. Before registration as a dental student every applicant should produce evidence that he has attained the age of 17 years.

PROFESSIONAL STUDY

Every candidate for a degree or licence in dentistry or dental surgery should be required before admission to the final or qualifying examination to produce certificates showing:

(i) That he is at least 21 years of age.

(ii) That he has been registered as a dental student.

(iii) That he has, subsequently to registration as a dental student, been engaged in professional study for at least four years, of which three years at least shall have been spent at a school or schools recognized for professional study by one of the licensing bodies.

(iv) That, subsequently to registration as a dental student, he has attended at a recognized medical or dental school courses of instruction which should be the same as those for medical students, in (*a*) chemistry, and (*b*) physics, in their application to medicine and dentistry, (*c*) elementary biology. (A student who has diligently attended an approved course of elementary biology in a teaching institution recognized by a licensing body may be admitted to a professional examination in elementary biology immediately after his registration as a dental student.) That he has attended at a recognized medical school courses of instruction, *specially adapted for students in dentistry*, in the following subjects: (*d*) human anatomy, including dissections for three academic terms of nine months. This should include not less than 40 lectures and/or demonstrations. The course of dissections shall include dissections of the head and neck. (*e*) Physiology (with laboratory instruction) extending over two academic terms of six months. This should include not less than 40 lectures and/or demonstrations; also a practical course in chemical and experimental physiology of not less than 30 hours. (*f*) Histology should consist of a practical course of not less than 40 hours. (*g*) General pathology for two academic terms (not less than 40 lectures and/or demonstrations). (*h*) Bacteriology for one term (not less than 10 lectures and 24 hours' practical work). (*i*) Medicine for two academic terms or six months (not less than 30 meetings of the class). (*j*) Surgery for two academic terms or six months (not less than 40 meetings). (*k*) Clinical instruction in a recognized general hospital on selected cases in medicine and in surgery over a period of at least nine calendar months, including instruction in venereal diseases with any bearing on dentistry. Each of these courses should consist of not less than 50 meetings. It is desirable that the systematic courses in medicine and surgery and the clinical instruction should, so far as possible, be co-ordinated. The course of instruction in medicine, surgery, and pathology should normally be taken after the student has passed the examinations in human anatomy and physiology.

(v) That he has attended at a recognized dental school courses of instruction in: (*a*) Special anatomy, human and comparative. The course should comprise a minimum of 20 meetings of the class. (*b*) Practical normal and morbid histology (16 meetings). (*c*) Dental surgery (20 meetings). (*d*) Materia medica and therapeutics (10 meetings). (*e*) Metallurgy with practical work and demonstrations (16 meetings). (*f*) Dental mechanics and prosthetics (20 meetings). (*g*) Instruction in the use of anaesthetics employed in the practice of dentistry. (*h*) Instruction in radiology and its application to dentistry. (*i*) The principles of orthodontics (10 meetings).

(vi) That he has for at least two calendar years attended the practice of a recognized dental hospital or of the dental department of a general hospital recognized by a licensing body as forming part of a dental school.

(vii) That he has received for not less than 24 calendar months, or for 2,000 hours, practical instruction in dental mechanics. No portion of such practical instruction which is taken before registration shall be reckoned as a portion of the four years of professional study required, but in the event of hardship arising in a particular case, an application for exceptional treatment may be submitted to the Education Committee of the General Medical Council. It is recommended that practical instruction in dental mechanics shall be taken at a recognized dental hospital and school. If any part of such instruction be taken by the candidate as a pupil with a registered dentist, the time devoted to it shall be at least twice the time required for the corresponding instruction taken at a dental school.

PROFESSIONAL EXAMINATIONS

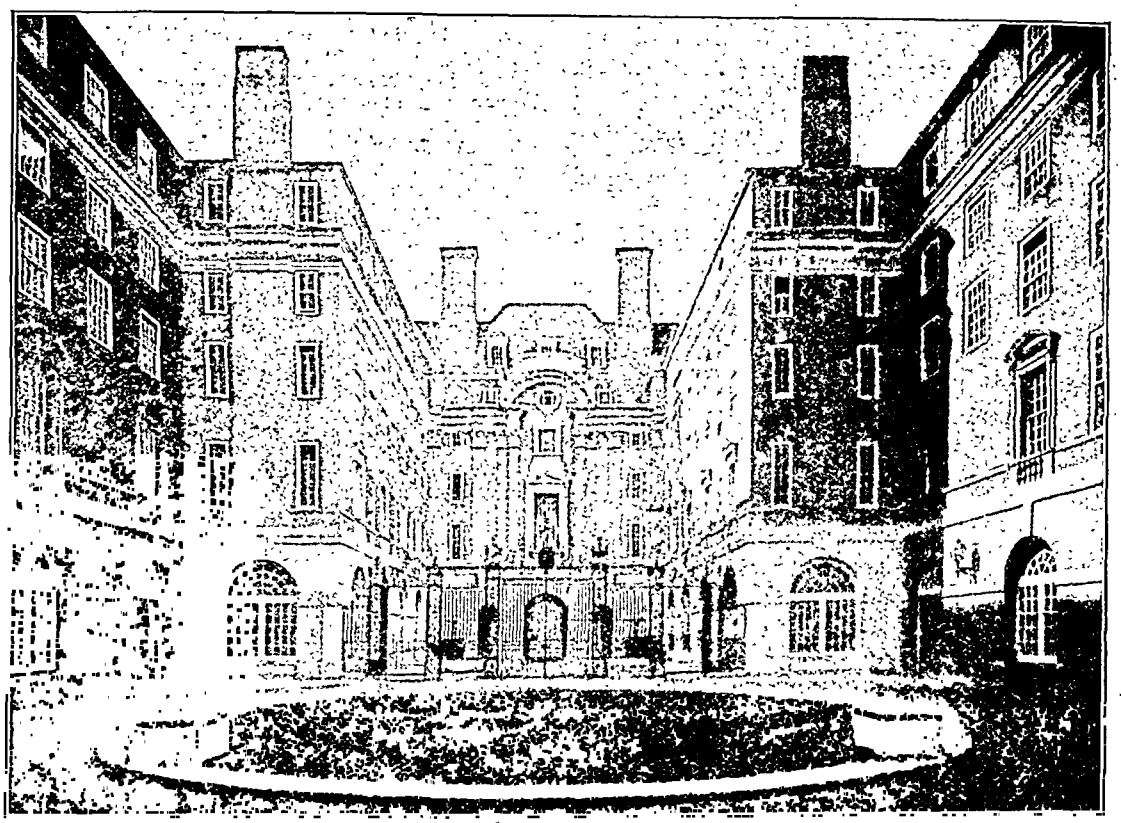
The examinations for a degree or licence in dentistry should be partly written, partly oral, and partly practical, and should include the following subjects: (*a*) Chemistry, Physics, and Biology in their bearing on medicine and dentistry. (*b*) Human anatomy, the oral examination in which should be conducted mainly on dissections, especially of the head and neck. (*c*) Physiology, the oral examination in which should include practical physiological tests. (*d*) Histology, which may be included in the examination in either anatomy or physiology. (*e*) General pathology, the oral examination in which should be conducted with the aid of specimens, including those of diseases connected with dentistry. (*f*) Bacteriology, the oral examination in which should include simple practical tests. (*g*) Medicine and surgery, the oral examinations in which should include a clinical examination of patients. (*h*) Special anatomy, human and comparative. (*i*) Dental mechanics, prosthetics and metallurgy, including practical tests. (*j*) Dental surgery, including special pathology and histology, materia medica and therapeutics, and the principles of orthodontics. (*k*) Practical dental surgery, which should include the usual dental operations —for example, filling and extraction of teeth and the giving of anaesthetics—and a clinical examination on the diagnosis and treatment of dental disease and abnormal conditions of the oral cavity.

A candidate should produce a certificate of having administered general anaesthetics on at least ten occasions.

ACKNOWLEDGEMENT

The detailed information published in this Educational Number of the *British Medical Journal* for the benefit of intending students of medicine and newly qualified practitioners has been revised throughout with the co-operation of the deans and secretaries of the medical schools and kindred institutions and of officials in the several public services, to all of whom we wish to acknowledge our indebtedness.

Sterilization of Surgical Ligatures



The Minister of Health has issued new regulations, which will come into force on October 1, requiring all surgical ligatures and sutures, including catgut, which are not sold under the special licensing arrangements of the Therapeutic Substances Act of 1925 to bear a label stating in prescribed terms that efficient sterilization is necessary before use. Catgut sold under the Minister's licence is free from any possible risk of infection, as its manufacture is strictly controlled and it is properly sterilized before being offered for sale. Deaths, however, have been known to occur from the use of ligatures (including catgut not sold under licence) which have not been properly sterilized, and the Minister drew special attention to this risk in a memorandum issued just a year ago to county and county borough councils and, through the British Hospitals Association, to every voluntary hospital in England and Wales (*Journal*, September 26, 1936, p. 636). The new regulations introduce a fresh safeguard by making it easy to distinguish other ligatures and sutures from properly sterilized catgut.

[The present issue being the Annual Educational Number, much current material is held over, and the "Epitome of Current Medical Literature" is not published this week.

The British Medical Association

ITS AIMS, WORK, AND CONSTITUTION

The British Medical Association, as stated in our introductory article on the Profession of Medicine, was founded in 1832 to promote the medical and allied sciences, to maintain the honour and interests of the profession, and to foster a feeling of friendship among its members. To attain these objects it holds meetings, local and central, for the discussion of medical and scientific subjects and of professional affairs ; it publishes the *British Medical Journal* and other scientific publications ; it maintains a reference and lending library ; it has instituted lectures, and scholarships and grants in aid of research. It concerns itself with every side of medical work, and much of the Association's daily work consists in aiding individual members in solving professional problems. The Association is the oldest, largest, and most powerful British organization devoted to the welfare of the medical profession. Its membership is now 36,000. It has a fine building in Tavistock Square, London, for its headquarters. These premises, designed by Sir Edwin Lutyens, R.A., were formally opened in 1925 by King George V, Patron of the Association.

British Medical Association House, London

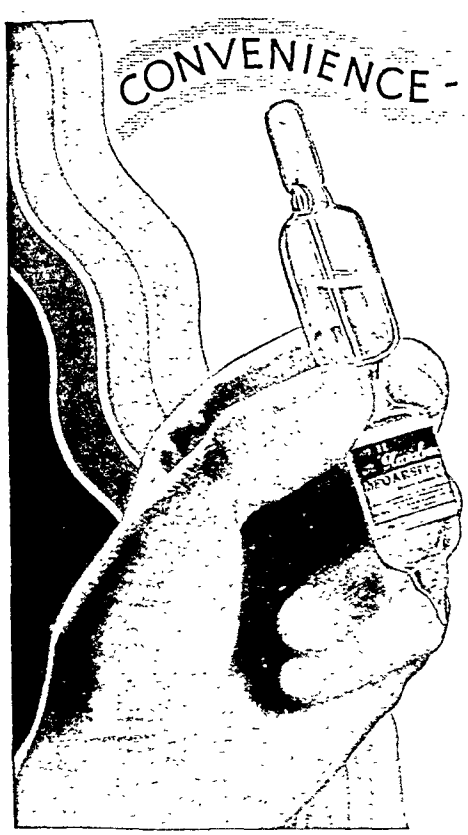
Constitution and Administration

The Association has Branches and Divisions throughout Great Britain and Northern Ireland, and also in the Dominions, Colonies, and Dependencies. Thus there are 43 Branches and 189 Divisions in Great Britain and Northern Ireland, and 68 Branches and 64 Divisions in the British Empire over-seas. The Branches in Australia and South Africa are linked up in Federal Councils for these respective areas. The Irish Free State Medical Union (I.M.A. and B.M.A.) was formed at the beginning of last year, and is now a corporate group of Branches and Divisions within the Association. To the Association there is affiliated the Canadian Medical Association. Members of Divisions elect representatives on the Branch Councils and also a member or members of the Representative Body, which is the governing body of the Association and determines its policy.

The Council is the executive of the Association. It is elected partly by the Divisions and Branches and partly by the Representative Body, and includes representatives of the public health service, Navy, Army, Air Force, and Indian Medical Services. The Representative Body and Council elect standing committees to take charge of different subjects. Among these may be mentioned the Science, Medico-Political, Ethical, Hospitals, Public Health, and Naval and Military Committees. There are Committees also for the Dominions, Scotland, and Wales ; and for the working machinery of the Association, such as the Organization, Finance, and Journal Committees. The Insurance Acts Committee, elected partly by the Association and partly by insurance medical practitioners, is the recognized executive and mouthpiece of the insurance practitioners of Great Britain and Northern Ireland.

Privileges of Members

A member of the Association has the right—



1. To attend the annual and other general meetings of the Association and the meetings of the Division and Branch to which he or she belongs.
2. To receive by post the *British Medical Journal*, published weekly, which gives a full record, with commentary, of progress in clinical and scientific medicine, and of medico-political affairs and medical economics.
3. To take part in the election of the representative of his or her Division in the Representative Body, and also in the election of members of the Council.
4. To receive the help and advice of the central office in any professional difficulty.
5. To use the Library as a reading room, and to borrow current medical or scientific books on payment of postage.

The full benefits of the Association can be secured only by the co-operation of large numbers of the medical profession, for the greater the membership and the funds the more efficient and influential the organization. A generous concession is made as regards subscription for those recently qualified, for whom the Association has done much in improving the conditions of appointments in the public services or in civil life. The Association's work for the Services is well known. It feels a special responsibility towards those members of the profession who by reason of their position are precluded from taking common action.

Subscriptions and Applications for Membership

The ordinary subscription to the British Medical Association is 3 guineas a year for members resident in Great Britain and Northern Ireland, but this is subject to exceptions. Thus, newly qualified practitioners elected within two years of registration pay half this sum up to the end of the fourth year after registration; medical officers on the active list of the R.N., R.A.F., R.A.M.C. (Regular), and I.M.S. pay 2 guineas ; concessions are made also to members (in the British Isles) of forty years' standing, to members of ten years' standing who have retired from practice, to medical married couples residing together, and to certain whole-time teachers and research workers. The ordinary subscription for members living abroad is 1½ guineas, but many over-seas Branches have special local subscriptions. After fifty years of membership no further subscription is payable. A member elected after June 30 pays half the subscription for that year.

All duly qualified British medical practitioners are eligible for election. Full particulars can be obtained from the Secretary, B.M.A. House, Tavistock Square, London, W.C.1.

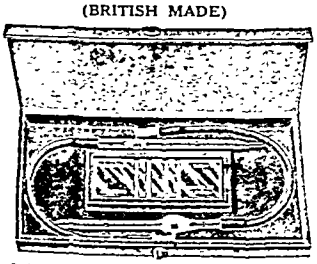
BRITISH MEDICAL FINANCE LIMITED, TAVISTOCK HOUSE SOUTH, TAVISTOCK SQUARE, W.C.1

Socks of character

It is an interesting fact that the wool used for Two Steeples No. 83 Socks is of the same high grade as used for the "quality" suitings bought by the best tailors. The No. 83 Sock is, in fact, a close relative to the English and Scottish cloths that are famous throughout the world, the only difference being in the way the yarn is spun. This is to meet the technical requirements of the knitting machine as distinct from the weaving loom.



Your hosier will be pleased to show you this sock, made in a shade for every suit. Sizes 8½ to 12", 4/6 per pair.

Pattern booklet of wide range of quality socks and underwear sent on request to Dept. 4, "Two Steeples" Ltd., Wigston, Leicestershire.

PARK ROYAL ROAD, LONDON, N.W.10

THE GUARANTEES OF EFFICACY

Aluzyme is plain Brewers' Yeast, stabilised by dehydration at a low temperature. This leaves the cells intact; Aluzyme contains 95% of vital cells and therefore provides all the essential constituents of yeast in the fully active state of living substance. Officially certified Vitamin potencies: B_1: 1140 Internat. Units per ounce. B_2 Complex: Maximum for Dried Yeast. Sulphur content, 0.47%; Nuclein, 0.4%. Glutathione reaction, brilliant magenta. Its therapeutic value in B avitaminosis, furunculosis, and the Anaemias is apparent from these particulars.

In the treatment of

VARICOSE VEINS

and most leg complaints doctors prescribe **Compri-Vena** SURGICAL STOCKINGS

THEY are invaluable in cases of varicosity and after injection treatment as well as during and after pregnancy. They are also widely recommended in cases of undue swelling or fatigue caused by standing for long periods.
Being made only to individual measurement assures the exactness of fit essential to treatment. They contain no rubber and are therefore cool, comfortable, hygienic and washable. As they are invisible under fine hose the wearing of them does not in any way embarrass the patient. Full details from

Rly.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS
NORTHAMPTON.
FOR THE UPPER AND MIDDLE CLASSES ONLY

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, and X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate, a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton), who can be seen in London by appointment

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Occupational Therapy. Voluntary and Temporary Patients received.
Tel.: 64117. *For terms, etc., apply to the Medical Superintendent.*

HAYDOCK LODGE
NEWTON-LE-WILLOWS, LANCASHIRE

Teleg.: Street, Ashton-in-Makerfield. *Phone*: Ashton-in-Makerfield 7311.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES suffering from mental and nervous diseases, either voluntarily, temporarily, or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT

COURT HALL, KENTON, near EXETER,
for the treatment of eight Ladies, voluntary, temporary, or certified patients
Large gardens and own dairy

CLIFFDEN, TEIGNMOUTH, for early and convalescent cases. A well-appointed house, with spacious balconies, and extensive views of the South Devon coast. Sub-tropical gardens, own dairy in 25 acres. Private road to beach.

Telephones: Starcross 59 Teignmouth 289

NORTHUMBERLAND HOUSE,
GREEN LANES, FINSBURY PARK, N.4.

A PRIVATE HOSPITAL for the treatment of mental and nervous illnesses. Conveniently situated and easy of access from all parts. Six acres of ground, highly situated, facing Finsbury Park. Voluntary and Temporary Patients received without certification. Occupational Therapy, Psychotherapy, and other modern forms of treatment.
Telephone: STAMFORD HILL 2033. Telegrams: "SUBSIDIARY, LONDON."
Convalescent Home, KEARSNEY COURT, DOVER. For further particulars, apply to the Medical Sup.

BETHLEM ROYAL HOSPITAL, for Nervous and Mental Disorders

Monks Orchard, Monks Orchard Road, Eden Park, Beckenham, Kent.

Reg. Tel. Address: Bethlem, Beckenham. *Station:* Eden Park (Southern Railway). *Telephone:* Springpark 1180-1181.

President: VISCOUNT WAKEFIELD OF HYTHE, G.C.V.O.
Treasurer: SIR LIONEL FAUDEL-PHILLIPS, Bart.
Physician-Supt.: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure, and farm grounds.
Applications can be considered on behalf of patients of the educated classes in a presumably curable condition.
With a view to early treatment voluntary or uncertified patients are admitted.
Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge.
Every facility for specialized investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found *X*-Ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.
Furthermore, provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms, and Occupational Therapy under competent instruction is encouraged.
In addition to the Resident Medical Staff, Consultants in special branches of medicine and surgery are available whenever required.
The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.
For forms and further particulars apply to the Physician-Superintendent at the Hospital.

PSYCHOTHERAPEUTIC THEORY AND METHOD

will begin on October 4th, 1937.

Lectures will be given on Monday and Thursday afternoons.

A course of ten lectures on

THE NEUROSES IN GENERAL PRACTICE

will be given on Thursdays at 8.30 p.m., beginning October 7th.

Full details from the EDUCATIONAL SECRETARY at the CLINIC.

UNIVERSITY OF DUBLIN
SCHOOL OF PHYSIC, TRINITY COLLEGE.

The usual three weeks' Post-graduate Course for General Practitioners will be held this autumn from Monday, September 20th, to Friday, October 8th. The course will include clinical instruction in Surgery (including Orthopaedics), Medicine (including Neurology, Cardiology, Fevers, Children's Diseases and Skin Diseases), Obstetrics and Gynaecology, and Diseases of Eye, Ear, Nose and Throat. Instruction will be given each afternoon in the Medical School in Clinical Pathology, Bacteriology, Physiology and Biochemistry. There will also be demonstrations on the uses of Radium and lectures on Medicine and Therapeutics. Fee for the course, five guineas.

For further particulars apply to:—

Professor DAVID S. TORRENS
School of Physic, Trinity College, Dublin.

THE LONDON HOMOEOPATHIC HOSPITAL

(Incorporated by Royal Charter)

GREAT ORMOND ST., & QUEEN SQUARE, W.C.1.

Education Facilities for Graduates and Senior Students of Medicine.

WINTER SESSION, 1937-38

HONYMAN-GILLESPIE LECTURESHIP

29th Year.

A Course of Lectures on **HOMOEOPATHIC MATERIA MEDICA AND THERAPEUTICS**, accompanied with **CLINICAL DEMONSTRATIONS**, will be given by CHARLES E. WHEELER, M.D., B.S., B.Sc.Lond., Consulting Physician to The London Homoeopathic Hospital, at the Hospital, on

Mondays and Thursdays, October, 1937, to March, 1938, commencing Monday, October 18th, at 5 o'clock. On the First Thursday of the month the hour is 3.30 p.m.

The COMPTON-BURNETT LECTURES

A Course of Ten Lectures on **HOMOEOPATHIC PHILOSOPHY AND PRESCRIBING**, as illustrated from the writings of the Organon and Modern Developments therefrom, are given by Sir JOHN WEIR, K.C.V.O., M.B., Ch.B.Glasg. (Physician to His Majesty the King, Physician-in-Ordinary to H.M. Queen Mary, Senior Physician to The London Homoeopathic Hospital), at the Winter Session only on

Fridays at 5 p.m., October to December, commencing Friday, October 15th.

AN INTRODUCTORY LECTURE TO THE WHOLE EDUCATION COURSE will be delivered at The Hastings Hall, British Medical Association House, Tavistock Square, W.C.1, by kind permission of the British Medical Association on Friday, October 8th, 1937, at 5 p.m., by CHARLES E. WHEELER, M.D., B.S., B.Sc.Lond., entitled "A Hundred Years of a Heresy."

Medical Men and Women are invited to attend this Lecture.

TUTORIAL CLASS

A class for individual study of the Materia Medica by the Repertory and References to Patients will be conducted by DOUGLAS M. BORLAND, M.B., Ch.B.Glasg., Physician to The London Homoeopathic Hospital, on

Fridays, at 6.15 p.m., October to March, commencing October 15th.

CLINICAL TUTORIALS

On Monday and Friday afternoons, at 2 o'clock throughout both the Winter and Summer Sessions, the Medical Tutor to the Hospital, WILLIAM WILSON RORKE, M.B., Ch.B.Glasg., conducts an Out-patient Clinic for the purpose of instruction in the application of Homoeopathic principles.

THE SIR HENRY TYLER SCHOLARSHIP COMMITTEE

also offer SCHOLARSHIPS to Medical Men in the Provinces desirous of taking a Post-Graduate Course at the London Homoeopathic Hospital during the Ten Compton-Burnett Lectures.

MASTERY OF MIDWIFERY

OF THE SOCIETY OF APOTHECARIES OF LONDON (M.M.S.A.)

The Mastery of Midwifery is designed to give evidence of intensive study and practical experience in Ante-Natal Care, Midwifery, and Infant Welfare and their relation to Hygiene and Preventive Medicine.

The Diploma of the Mastery indicates competence to undertake the responsible control of Maternity and Child Welfare work.

The tests imposed are stringent; the examination, written, oral and clinical, demands thorough and detailed knowledge gained by practical experience and constitutes a definite endeavour to combat Maternal and Infant Mortality.

Examinations are held twice yearly, in the months of May and November.

Regulations and forms of application for admission to the examination may be obtained from:—

THE REGISTRAR, The Society of Apothecaries, Water Lane, E.C. 4

UNIVERSITY EXAMINATION POSTAL INSTITUTION

17, RED LION SQUARE, LONDON, W.C.1.

FOUNDED IN 1882 BY THE LATE E. S. WEYMOUTH, M.A.(Lond.). *Telephone*: Holborn 6313.

ST. MARY'S HOSPITAL MEDICAL SCHOOL, W.2

(University of London)

The WINTER SESSION will begin on Friday, October 1st, 1937.

EXCEPTIONAL SITUATION. The situation of the Hospital and Medical School is unique, for while it is adjacent to a large poor district with a population of 500,000, it is also within a few minutes' walk of Kensington Gardens, and an extensive residential district, in which students can live, and so avoid a daily wearisome journey to and from their work. Recent structural alterations include two new operating theatres and 75 additional beds.

REBUILDING OF THE MEDICAL SCHOOL. Approximately £250,000 has been spent in rebuilding the Medical School and Laboratories. The New Buildings are now in use. Apart from the Laboratories, Class-rooms and Theatres for all the subjects in the Curriculum, they include a Library, Restaurant, Students' Club, Billiard Room, Swimming Bath, Squash Rackets Court, Gymnasium, Boxing Ring, and an underground Garage for fifty cars

COMPLETE CURRICULUM. The entire Curriculum is provided and students may join the School at once after matriculation.

SPECIAL CLINICAL FACILITIES The formation of Clinical Units in Medicine and Surgery has been an important advance in connection with the Clinical teaching, and this has been further developed by the affiliation for teaching purposes of several of the Hospitals in the neighbourhood, bringing up the total number of beds, available for teaching, to 1,000. By agreement with Queen Charlotte's Lying-in Hospital, all students of St. Mary's attend a short course of instruction there, without extra fee, before entering upon their duties in the Maternity District of St. Mary's.

INSTITUTE OF PATHOLOGY AND RESEARCH. The Institute of Pathology and Research, under the directorship of Sir Almroth Wright, F.R.S., embraces seven departments, the heads of which are members of the Honorary Staff of the Hospital.

RESEARCH STUDENTSHIPS A considerable sum is devoted annually to research, and a part of this is applied to the upkeep of Research Scholarships, designed to enable students recently qualified to learn the technique of research work.

ENTRANCE SCHOLARSHIPS All Entrance Scholarships are awarded annually by nomination.
The Geraldine Harmsworth Scholarship (£200), and other University Scholarships, are open to members of British Universities who have completed their examination in Anatomy and Physiology.

APPOINTMENTS AFTER QUALIFICATION. Numerous appointments are open to newly qualified members of the Medical School. Six House Physicians (eight months), Ten House Surgeons (six to eight months), and Four Resident Obstetric Officers (six months) are appointed annually. Two Resident Anaesthetists (six months), £150 per annum, Four Casualty House Surgeons (six months), £100 per annum, with board and residence, Two Medical Registrars and Surgical Registrar, £200 per annum, with partial board. Obstetric Registrar and Radium Registrar, each £50 per annum, with partial board.
In addition to the above, Five Assistants to the Medical and Surgical Units are appointed from time to time, with salaries ranging from £400 to £750 per annum.

ATHLETIC GROUND. The Old Merchant Taylors Ground (13 acres) has been acquired. On sand, it remains dry throughout the winter.

The Illustrated Prospectus can be obtained from the School Secretary, St. Mary's Hospital, Paddington, W.2.

C. M. WILSON (*M.C.*), M.D., F.R.C.P., Dean.

DIPLOMA IN PUBLIC HEALTH, &c.

Jan.	6	Disproportion and Difficult Labour	Mr. LESLIE WILLIAMS, M.D., M.S., F.R.C.S., F.C.O.G.
„	13	Disproportion and Difficult Labour (contd.)	Mr. LESLIE WILLIAMS, M.D., M.S., F.R.C.S., F.C.O.G.
„	20	Caesarean Section	Mr. J. BRIGHT BANISTER, M.A., M.D., F.R.C.P., F.R.C.S., F.C.O.G.
„	27	Anaesthesia and Analgesia.	Prof. J. CHASSAR MOIR, M.D., F.R.C.S., F.C.O.G.

These lectures are for regular students of the School, but a limited number of tickets are available, without fee, to medical practitioners.

Applications for tickets should be addressed to the Dean, British Postgraduate Medical School, Ducane Road, W. 12.

NEUROLOGY AND PSYCHOPATHOLOGY

CLINICAL INSTRUCTION AT THE

WEST END HOSPITAL FOR NERVOUS DISEASES

WELBECK STREET, W.1

D.P.M. (Conjoint Board). A two-months' course, approximately half-time, in Neurology, suitable for Part II of this examination will be held during October and November, 1937. The course will be chiefly in the afternoons and will include clinical demonstrations in neurology and the psychoneuroses with special demonstrations in neuropathology; neurological ophthalmology, radiology, and surgery, child guidance; the study of delinquency, etc. The course may be taken in whole or in part. Fee for the full course: £5 5s.

M.R.C.P.(Lond.). An intensive course in Neurology for this examination, with facilities for examination of cases, will be held in December, 1937.

Special Courses. These will be arranged during the year for those interested in, amongst others, the following subjects: the psychoneuroses and psychotherapy; study and treatment of delinquency; child guidance; speech training and speech records; medical ophthalmology; neurological orthopaedics and physiotherapy; neurological radiology.

Practice of the Hospital. Attendance upon this in the various departments for both in- and out-patients is open to practitioners at stated times. Fee: £2 2s. per month.

Senior Undergraduates. Facilities exist in the various departments of the hospital for the instruction of senior undergraduate students in neurology and related subjects. Fee: £1 1s. per month.

For particulars of the above apply to the Dean, T. Rowland Hill, M.D., M.R.C.P., or to the House Governor, West End Hospital for Nervous Diseases, London, W.1.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL

(The University of London) Albert Embankment, S.E.

The finest situation in London.

The WINTER SESSION begins on TUESDAY, OCTOBER 5th, 1937.

FULL CURRICULUM. Newly rebuilt and equipped Laboratories for Preliminary and Intermediate Subjects which are taught by Professors and Teachers recognized by the University of London. For Clinical work the fullest facilities are provided, including a special Maternity Ward, and liaison with St. James's Hospital, Balham, and with Lambeth Hospital.

UNIVERSITY MEN can join the School for any part of their M.B. Course, and for Clinical work can join in January, April, July, or October.

CLASSES for the PRIMARY and FINAL F.R.C.S. are held before each Examination.

A RESIDENTIAL HOSTEL and Students Club, with all amenities, is attached to the Hospital.

ENTRANCE SCHOLARSHIPS in SCIENCE and special UNIVERSITY SCHOLARSHIPS are awarded by Examination in July every year.

PROSPECTUS and full particulars may be obtained from the Secretary, The Medical School, St. Thomas's Hospital, London, S.E.1.

THE LONDON SCHOOL OF DERMATOLOGY
ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 5, LISLE STREET, LEICESTER SQUARE, W.C.2

The CHESTERFIELD LECTURES, constituting a systematic Course in Dermatology, will be given at 5 p.m. from October 5th to December 2nd, and during January and February, 1938.

SYLLABUS—WINTER SESSION

1937.	Subject.	Lecturer.
Oct. 5, Tues.	Eczema	Dr. W. GRIFFITH
„ 7, Thurs.	Animal Diseases Communicable to Man	Dr. M. SYDNEY THOMSON
„ 12, Tues.	Treatment of Some Common Skin Diseases	Dr. J. E. M. WIGLEY
„ 13, Wed.	Introduction to Histopathology of the Skin	Dr. I. MUENDE
„ 14, Thurs.	Ringworm Infections	Dr. J. M. H. MACLEOD
„ 19, Tues.	Psoriasis	Dr. H. W. BARBER
„ 20, Wed.	Histopathology of Common Skin Diseases	Dr. I. MUENDE
„ 26, Tues.	Electro-therapeutics	Dr. W. KNOWSLEY SIBLEY
„ 28, Thurs.	Dermatological Neuroses	Dr. W. J. O'DONOVAN
Nov. 2, Tues.	Skin Affections of the Hands and Feet	Dr. G. B. M. HEGGS
Nov. 4, Thurs.	Syphilis Through Four Centuries	Dr. H. CORSI
„ 9, Tues.	Malignant Growths of the Skin	Dr. H. MACCORMAC
„ 10, Wed.	Histopathology of Chronic Granulomata	Dr. I. MUENDE
„ 11, Thurs.	Seborrhoea and Seborrhoeic Dermatitis	Dr. G. B. DOWLING
„ 16, Tues.	Infantile Eczema and Papular Urticaria	Dr. W. N. GOLDSMITH
„ 17, Wed.	Histopathology of New Growths of the Skin	Dr. I. MUENDE
„ 23, Tues.	Cutaneous Affections due to Sunlight	Dr. HUGH GORDON
„ 25, Thurs.	The Sarcoids and Lupus Pernio	Dr. A. M. H. GRAY
„ 30, Tues.	Virus Diseases of the Skin	Dr. R. T. BRAIN
Dec. 2, Thurs.	Bullous Eruptions	Dr. J. L. FRANKLIN

A further Course will be held during January and February, 1938.

An Examination will be held at the end of the Course in March, and the CHESTERFIELD MEDAL will be awarded to the best candidate, provided the required standard is reached. An intensive Course will also be held during the month of May.

CLINICS.—Instruction will be given daily in the Out-Patient Department, as follows:—

Monday, 2 P.M.	Dr. GRIFFITH.	Wednesday, 2 P.M.	Dr. WIGLEY.	Friday, 2 P.M.	Dr. SIBLEY.
6 P.M.	Dr. DORE	6 P.M.	Dr. DOWLING.	6 P.M.	Dr. BRAIN.
Tuesday, 2 P.M.	Dr. FORMAN.	Thursday, 2 P.M.	Dr. CORSI.	Saturday, 2 P.M.	THE MEDICAL
6 P.M.	Dr. MUENDE.	6 P.M.	Dr. GOLDSMITH.		REGISTRAR.

LABORATORY.—Arrangements can be made for Classes, individual instruction, or for research work. For Particulars and Fees apply to the Dean.

FEES.—For Hospital Practice, including Lectures, One Guinea per month. Registered Medical Students may attend the Lectures free on signing their names and giving the name of their Hospital.

Medical Practitioners will be welcome as occasional visitors on presentation of their cards. For further particulars apply to Dean or Secretary.

LEONARD G. R. TURPIN, Secretary. J. E. M. WIGLEY, M.B., Dean.

THE HOSPITAL FOR SICK CHILDREN
GREAT ORMOND STREET, LONDON, W.C.1.
MEDICAL SCHOOL FOR POST-GRADUATES

THE HOSPITAL CONTAINS 257 BEDS. with an average admission of over 7,000 In-patients per annum, whilst in the Out-Patient Department about 30,000 new patients are seen each year.

THE MEDICAL SCHOOL is recognised by the Universities of Oxford, Cambridge and London and by the Conjoint Board of England, as a Teaching Institution where students receive instruction in the diseases of children for such period as is required by the regulations of the Conjoint Board.

POST-GRADUATE INSTRUCTION, open to all qualified medical men and women, is given daily at both morning and afternoon sessions. Morning sessions, 10 to 12 noon, include Medical and Surgical Out-patient Clinics; Ear, Nose and Throat Clinic, Wednesdays 12 to 1 p.m. Afternoon sessions include Ward Visits and Surgical operations; Eye Clinic once a week; Skin and Dental Clinics once a week; Morbid Anatomy Demonstration, Wednesday 11-12 noon. Instruction is also given in the Venereal Diseases Department, and in the use of Anaesthetics in dental and tonsillectomy operations.

There are three terms yearly, each of approximately 13 weeks, during which lectures (particulars of which are published in advance in the medical press) are given on Thursday afternoons:—Clinical, 2-3 p.m., and Clinico-pathological or Biochemical, 3 to 4 p.m.

Fees: One week, 1½ guineas; two weeks, £3 3s.; one month, £5 5s.; two months, 7½ guineas; three months, or whole term, £10 10s. Clinical Clerkships in the wards are available for 4th and 5th year undergraduates. Special Clinical Assistantships for Post-graduate students for periods of 3 months and upwards can be arranged.

SPECIAL COURSES IN PRACTICAL PATHOLOGY, consisting of six demonstrations, are also given at the Hospital. These courses demonstrate such methods as can be usefully carried out away from a laboratory and are of general application. Fee for each course £3 3s.

FULLER DETAILS may be obtained from the Secretary at the Hospital.

H. F. RUTHERFORD, Secretary. W. G. WYLLIE, Dean.

GUY'S HOSPITAL MEDICAL & DENTAL SCHOOLS.
(UNIVERSITY OF LONDON.)

THE HOSPITAL, which contains 681 Beds, is situated one minute's walk from London Bridge Railway Stations.

SPECIAL CLASSES are held in CHEMISTRY, PHYSICS, and BIOLOGY for the First M.B. Examination of the University of London and for the Pre-Medical Examination for the "Conjoint" and L.D.S. Diplomas.

THE WINTER SESSION will commence on TUESDAY, OCTOBER 5th, 1937.

ENTRANCE SCHOLARSHIPS.—MEDICAL SCHOOL.

The following Entrance Scholarships are awarded annually in the month of April.

A.—Open Junior Scholarships.—1. An ARTS SCHOLARSHIP of the value of £100. (2) A SCIENCE SCHOLARSHIP of the value of £100. 3. A WAR MEMORIAL SCHOLARSHIP of the value of £200, awarded alternately in Arts and Science. This Scholarship is open every other year; the next award will be made in 1938 in Science.

B.—Confined Scholarship in Science.—A JUNIOR SCIENCE SCHOLARSHIP of the value of £100 is offered to Candidates who have attended the Preliminary Science Classes at this School for a full academic year.

The following Entrance Scholarships are awarded annually in the month of June or July:—

C.—University Entrance (British Universities) Scholarships.—1. A WAR MEMORIAL SCHOLARSHIP the value of which shall be a free undergraduate medical education for a period of three years. 2. An EXHIBITION of the value of £60. These Scholarships are awarded on the results of an Examination which is held in common with the Medical Schools of St. Bartholomew's and St. Thomas's Hospitals. Subjects: Candidates will be examined in two of the following Subjects, at their option. (1) Human Anatomy and Embryology; (2) Physiology; (3) Organic Chemistry; (4) General Pathology, including Bacteriology.

THE DENTAL SCHOOL.

Offers Two Open Scholarships in April of each year: 1. A WAR MEMORIAL SCHOLARSHIP IN ARTS of the annual value of £40 for four years. 2. A SCIENCE SCHOLARSHIP of the value of £40 per annum for not more than four years.

Numerous Prizes, Medals, and Scholarships are open for competition during the period of Studentship.

For further particulars and for the Prospectus containing information as to the Course of Study advised, the Residential College, Fees, &c., application should be made either personally or by letter to *The Dean, Guy's Hospital Medical School, London Bridge, S.E.1.*

THE

METROPOLITAN EAR, NOSE, & THROAT HOSPITAL

(1838) (INCORPORATED),

FITZROY SQUARE, LONDON, W.1

FACILITIES FOR CLINICAL WORK are afforded to Medical Practitioners and Students. Fee for one month, 3 Guineas; for three months, 5 Guineas.

PRACTICAL DEMONSTRATIONS are given daily (Saturdays excepted) at 3 p.m., in the manipulation of instruments used in the Diagnosis and Treatment of Diseases of the Ear, Nose, and Throat.

CLINICAL ASSISTANTS are appointed as vacancies occur, and have responsible duties. Further particulars may be obtained from the Secretary. L. L. PHILLIPS.

LONDON SCHOOL of HYGIENE & TROPICAL MEDICINE

(University of London).

Incorporating the Ross Institute.

DIPLOMA IN PUBLIC HEALTH

The Course of Study for the UNIVERSITY OF LONDON DIPLOMA covers a period of nine months' whole-time work.

THE COURSE WILL COMMENCE ON SEPTEMBER 27th, 1937.

Inclusive FEE, 54 guineas, to cover lectures, demonstrations, the necessary practical work in public health departments, and instruction in infectious diseases, etc.

DIPLOMA IN TROPICAL MEDICINE AND HYGIENE (Eng.)

THE COURSE OF STUDY IS DIVIDED INTO TWO PARTS: Part I is a three months' course and Part II a two months' course. This Course of Study is recognised by the University of London as a Course for Associate Students.

DATES OF THE COURSES, 1937-8.

PART I. *September 27th—December 17th*, 1937. *January 3rd—March 25th*, 1938. *April 4th—June 24th*, 1938.

PART II. *January 17th—March 18th*, 1938. *April 19th—June 17th*, 1938.

Fees (inclusive): Part I, £25; Part II, £15.

DIPLOMA IN BACTERIOLOGY

The Course of Study for the UNIVERSITY OF LONDON DIPLOMA commences in October, 1937. Inclusive FEE £47 15s.

EPIDEMIOLOGY AND VITAL STATISTICS

Special Three-monthly Advanced Courses. Composition FEE, 7 guineas.

INDUSTRIAL PHYSIOLOGY & PSYCHOLOGY

Two courses are provided, one lasting a year and the other two weeks. The shorter course is restricted to persons with adequate industrial experience.

For Prospectuses, Synopses of Lectures, etc., apply to the SECRETARY, LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE, KEPPEL STREET (Gower Street), LONDON, W.C.1. (Museum 3041.)

NATIONAL HOSPITAL FOR DISEASES OF THE HEART

WESTMORELAND STREET, W.1.

The Clinical Practice of the Hospital in the Out-patient Department and the Wards is open to Post-Graduates. Fees: One Month, £2 2s.; Three Months, £5 5s.

Under-Graduates who have completed their fourth year are admitted to the Practice of the Hospital at specially reduced fees.

Special Courses of two weeks' duration are held in January-October only. Fee £7 7s.

Further particulars may be obtained on application to the Secretary at the Hospital.

Westminster Hospital Medical School

(UNIVERSITY OF LONDON)

The Medical School, centrally situated, is only a few minutes' walk from the Hospital. The entire teaching of the Hospital and School is devoted to the subjects of the Final Examinations. Arrangements are made for the tuition required for Preliminary and Intermediate subjects.

SESSIONS COMMENCE 1st WEEK IN JANUARY, APRIL, JULY, OCTOBER

OPENING OF NEW BUILDINGS.—The NEW MEDICAL SCHOOL, at present in course of construction in Horseferry Road, will be opened in 1938. Adjacent, on the opposite side of St. John's Gardens, the new WESTMINSTER HOSPITAL, of 400 beds, is rapidly approaching completion.

SCHOLARSHIPS.—Four Scholarships in Preliminary Subjects each to the value of £75 are offered in May of each year; Four Competitive Scholarships in Anatomy and Physiology each to the value of £75 are offered in April and September of each year

RESIDENT APPOINTMENTS.—Paid appointments as Medical, Surgical, and Obstetric Registrars, Casualty Officers, House Physicians, House Surgeons, and Anaesthetist, are available for Students upon qualification. There are excellent opportunities for research work in the endowed Carlill Laboratories. The number of students is strictly limited to ensure the maximum advantages of individual clinical teaching, and to afford the large majority of those who qualify the opportunity to secure one of these very valuable appointments.

FEES.—Annual composition fee £42, which includes membership of the Sports Union with its various branches and allied clubs—football, cricket, tennis, hockey, boxing, swimming, fencing, sailing, and Guthrie Society. The Sports ground is within 20 minutes of the Hospital.

The Dean or Sub-Dean will be pleased to arrange for intending students and parents to inspect the Hospital and Medical School at any time. Only Male Students are admitted.

A Prospectus and full particulars may be obtained on application to the Dean:—

ADOLPHE ABRAHAMS, O.B.E., M.A., M.D., F.R.C.P.,
Westminster Hospital Medical School, Caxton Street, Westminster, S.W.1
Telephone: Whitehall 3665.

Charing Cross Hospital Medical School

(University of London)

Sessions begin October and April.

Complete arrangements for Subjects of the whole Medical Curriculum, with special departments for every branch of Clinical work.

"FIRMS."—Only thirty students are admitted each year. Every medical clerk and surgical dresser is therefore assured of having not less than six beds in his personal care.

THE INSTITUTE OF PATHOLOGY, with the abundance and variety of its material and fully equipped laboratories, offers exceptional advantages in this subject.

THE STUDENTS' UNION includes Common Rooms and Restaurant on the School premises, and a Sports Ground of 8 acres within half an hour's journey of the School.

RESIDENT APPOINTMENTS.—The large number of Resident Appointments (27 annually) in proportion to the number of students make it probable that all students of average ability will be able to secure election to the House Staff.

SCHOLARSHIPS. — The following are awarded annually:—(I) Three "University" Scholarships, each of the value of £120. Examinations are held in July; Subjects (a) General Pathology; (b) Anatomy and Physiology. (II) One "Open" Scholarship of the value of £75, and (III) two "Entrance" Scholarships of £50 each. In addition numerous Exhibitions and Prizes are awarded each year.

Men Students only are admitted.

Fees 38 Guineas per annum.

For Prospectus and full information apply personally or by letter to the Dean:—

ERIC A. CROOK, M.A., M.Ch., F.R.C.S.,
Charing Cross Hospital Medical School, 62, Chandos Place, London, W.C.2.

Telephone: Temple Bar 3903 and 3904

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL

(UNIVERSITY OF LONDON).

Dean: JOHN A. DRAKE, M.D. (Lond.), F.R.C.P., D.P.H.

THE NEW MEDICAL SCHOOL (opened in July, 1933) contains Lecture Rooms, Lecture Hall, Museum, Research Rooms and Laboratories, Bio-Chemical Research Laboratory, Common Rooms, and Refectory. Two new Squash Rackets Courts adjoin the School.

FOURTEEN ENTRANCE SCHOLARSHIPS, total value £1,530, are awarded annually.

RESIDENT HOSPITAL APPOINTMENTS, numbering thirty-one, are made during each year.

ATHLETIC GROUND. The Athletic Ground of the Medical School is within ten minutes' walk of the Hospital, and has accommodation for cricket, football, hockey, and lawn tennis.

SCHOOL HOSTEL. "The Platanes," standing in large grounds, with three lawn tennis courts, provides residence for 80 students, and is within five minutes' walk of the Hospital.

The Dental School was opened in October, 1923. A full Course is given in co-operation with King's College in preparation for Dental Degrees and Diplomas.

For Particulars, Calendar of the School, and Appointments to see the School and Hospital, application should be made to the Secretary, S. C. RANNER, M.A.Cantab., King's College Hospital Medical School, Denmark Hill, London, S.E. 5.

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL

(UNIVERSITY OF LONDON)

THE WINTER SESSION BEGINS ON OCTOBER 4th.

The entire Medical Curriculum can be taken at this School. Annual value of Scholarships and Prizes £1,000. Large Research Funds.

ENTIRE CURRICULUM.—THE PROVISION WHEREBY ALL THE SUBJECTS OF THE CURRICULUM, INCLUDING CHEMISTRY, PHYSICS AND BIOLOGY, FOR THE PRE-MEDICAL EXAMINATION, ARE TAUGHT WITHIN THE PRECINCTS of the HOSPITAL and MEDICAL SCHOOL, and every effort made to encourage co-ordination, ensures that the student, instead of proceeding to the study of the various subjects as if they were isolated and having little or no relation to each other, is taught each subject by professors and lecturers who are instructing medical students only, and are in close touch with all the other departments of the School. The rebuilding of the Hospital is complete and those working in the Institution have facilities equal to, or superior to, those to be found in any other hospital in the United Kingdom. The new buildings are not confined to the wards, but include a new Out-patients' Department, the Institute of Biochemistry, and new Departments for Diseases of Children, Neurology, Dermatology, etc. In addition, there is open a new Unit devoted to Clinical Research, and it contains six small self-contained wards and a large Clinical Lecture Theatre. The newly built quarters for the Resident Officers have been enlarged and afford greatly improved facilities. The following description of the work in various departments is designed to show how co-ordination is carried out.

CHEMISTRY is taught by Professor W. B. Tuck, and the class-room and laboratories are in the immediate vicinity of those for anatomy, physiology, pharmacology, pathology, and bacteriology. This leads to a close association with these departments, and the student realises he is not learning just the chemistry which he requires for his first professional examination, but is acquiring knowledge which he will need and have to apply in later years.

THE DEPARTMENT OF PHYSICS is under the charge of Professor Sidney Russ, who is also Physicist to the Hospital and engaged in research work involving the use of X-rays, Radium, Ultra-Violet Rays, and other forms of radiation. He is therefore in close touch with the departments of physiology and pathology, and takes an active part in departments for clinical therapeutics. Under his direction the student will realise at once that he is not studying an isolated subject for the purpose of training his mind or simply to comply with regulations and pass an examination, but is in touch with a subject which will be of great and increasing importance in the proper understanding of his work in later years.

BIOLOGY.—The Lecturer on Biology is Dr. J. H. Woodger, who holds a University Readership in this subject. His teaching in biology is characterized by co-ordination with other departments, and the bearing of the subject on the later stages of the curriculum is emphasized. Not only is the subject taught as an introduction to the study of Anatomy and Physiology, but the increasing importance of a knowledge of the lower forms of vegetable life and of the protozoa in the causation of disease and the study of insect carriers of human diseases is emphasized by co-ordination with the Pathological Institute.

IN THE DEPARTMENT OF ANATOMY, under the direction of Professor John Kirk, with the general scientific study of Anatomy and its wider Biological aspects, the relation of structure to function and pathology is not lost sight of. Facts of clinical medicine and surgery, of pathology, biology, and physiology, are included in the teaching in order to emphasize the significance of anatomical points. By classes in Applied Medical and Surgical Anatomy the study of this subject is continued in the later stages of the student's career.

THE TEACHING OF PHYSIOLOGY is in the hands of Professor Samson Wright, and the department is in close touch with those for the teaching of both the preliminary and final subjects of the curriculum. It is impressed upon the student in this department that he cannot be a good clinician unless he obtains a sound knowledge of Physiology, and physiological teaching is made to overlap the later periods of tuition by lectures on applied Physiology which are given by the Professor to students during their Clinical Period. Again, while in the wards the student has continuous opportunities of applying what he has learnt in the Physiological department, and his physiological knowledge is further extended, notably in the study of PHARMACOLOGY and in the CARDIOGRAPHIC Department, where he has opportunities of studying the electrical conditions of the heart both in health and disease.

IN THE BLAND-SUTTON INSTITUTE OF PATHOLOGY all the departments of the Medical School are brought in touch. Here the student learns the SCIENCE OF DISEASE. The teaching of Pathology is in the hands of Professor J. McIntosh, and under his tuition the student is made to realise that Pathology and Medicine are one and that a clear knowledge of Pathology and Bacteriology is essential for the prevention, diagnosis, and treatment of disease. The teaching of Pathology is brought into the closest touch with clinical teaching, and the student sees the practical application of the sciences in which he has been instructed in the earlier years of the curriculum.

THE COURTAULD INSTITUTE OF BIOCHEMISTRY is a building fully equipped with laboratories for teaching and biochemical research. Professor E. C. Dodds, who is in charge of the Department, holds complete courses in Biochemistry for students, both in their early years and during their period of instruction in the wards. In addition to this the student here acquires constant practical experience of the important modern chemical investigations necessary for the detection of disease and the study of its evolution. Several valuable post-graduate appointments in this Institute become available to students showing special ability in this direction.

CLINICAL TEACHING is carried out in the general wards and out-patients' departments, and in the special departments, all of which are in close touch with the scientific departments in the School. The student has ample opportunities for carrying out the physical examination of patients, and with his training on the scientific side combines instruction in the Art of Medicine by constantly being brought in contact with patients and being made to realise the human side of his professional work.

There are ample clinical appointments for all students, and 34 Resident appointments are open annually to students of the School who have obtained their degrees or diplomas. In addition, 12 Registrars are appointed annually.

RESIDENTIAL COLLEGE. Accommodation for a limited number of students is provided in the Hospital.

THE SOCIAL AND ATHLETIC side of the student's life is also studied, and these facilities include a Medical Society, a Common Room Society, and Athletic grounds. The Clubs include Rugby Football, Association Football, Golf, Cricket, Hockey, Sailing, Swimming, etc. A Squash Racket Court is also available.

A Prospectus may be obtained from the Secretary, R. A. FOLEY, F.C.C.S., The Medical School, Middlesex Hospital, London, W.1.

H. E. A. BOLDERO, M.A., D.M., F.R.C.P., DEAN.

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE

(UNIVERSITY OF LONDON)

WINTER SESSION BEGINS OCTOBER 1st, 1937.

THE HOSPITAL has **762 Beds** and the **MEDICAL COLLEGE** contains large Lecture Rooms and Laboratories, as well as a Museum and a Library.

Every Special Branch of Medicine and Surgery has a Department.

ENTRANCE SCHOLARSHIPS.

Eight Entrance Scholarships and Exhibitions are awarded annually of the aggregate **value** of **£900.**

Other Scholarships and Prizes amount to about **£1,000** annually.

PRELIMINARY SCIENCES.

Chemistry, Physics, and Biology are fully taught in the **Laboratories** allotted to these subjects.

All the pre-clinical Departments have now been transferred to the new site in Charterhouse Square, formerly occupied by the Merchant Taylors' School.

HOSPITAL APPOINTMENTS.

Over 100 Hospital Appointments (39 resident) are available each year for Students who have passed their final qualifying examination.

Five hundred and sixty Ward Clerkships and Dresserships are open annually to Students before qualification.

STUDENTS' UNION.

The Union possesses a Club Ground of seventeen acres at Chislehurst, and athletic amenities are available on the newly-purchased site in Charterhouse Square, five minutes' walk from the Hospital.

HIGHER EXAMINATIONS.

Special Classes are held for **F.R.C.S.,** etc.

For further particulars apply, personally or by letter to

THE DEAN OF THE MEDICAL COLLEGE, ST. BARTHOLOMEW'S HOSPITAL, LONDON, E.C.1.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL

(UNIVERSITY OF LONDON)

HYDE PARK CORNER, S.W.

THE HOSPITAL and MEDICAL SCHOOL occupy the finest site in London and are readily accessible from all parts of the Metropolis.

The entire teaching in the School is devoted to the subjects of the Final Examinations; in other words, **is specially adapted to the interests of men from the Universities who have passed their Examination in Anatomy and Physiology**

St. George's Students attend at King's College for tuition in the Preliminary and Intermediate subjects.

SEVEN ENTRANCE SCHOLARSHIPS IN ANATOMY AND PHYSIOLOGY, AND GENERAL PATHOLOGY, of the value of £120, £80 (3), £60 (2) and £50 respectively, are offered for competition in July to candidates who have passed the 2nd M.B. or corresponding examination. In addition, EXHIBITIONS, each of the value of £40 and up to *Four in* number, will be awarded to candidates of approved merit in the Entrance Scholarship Examination.

MANY VALUABLE PRIZES ARE AWARDED EACH YEAR, including the following: Allingham Scholarship of the value of £87, Laking-Dakin Memorial Prize of the value of £115, the *Brackenbury Prize in Medicine*, the *Brackenbury Prize in* Surgery, and the Webb Prize in Bacteriology each of the value of £33

RESIDENT HOUSE APPOINTMENTS. Eight Casualty Officers, ten House Surgeons, and eight House Physicians are appointed annually. They are provided with board and lodging in the Hospital and receive honoraria of £40 per annum. In addition, the following resident appointments are open to all qualified students of the Hospital: Resident Obstetric Assistant (two annually) and Resident Anaesthetist (two annually). They are provided with board and lodging and receive salaries of *£100 per annum. There are also five further senior appointments*, namely, one Resident Assistant Physician with a salary of £250 per annum, *two Surgical Chief Assistants, also resident*, with salaries of £200 per annum, and two Medical Registrars non-resident, with salaries of £100 per annum.

The ST. GEORGE'S HOSPITAL CLUB incorporates the RUGBY FOOTBALL, CRICKET, LAWN TENNIS, BOXING, *RIFLE* and other Clubs, and possesses an *ATHLETIC GROUND* within easy reach of the Hospital, and Smoking and Luncheon *Rooms on the School Premises.*

Entrance Fee, £10 10s. 0d. Annual Composition Fee, which covers all courses, lectures, etc., in the Hospital and School, £42. Annual Club Subscription, £3 13s. 6d.

The Winter Session will begin on October 1st, but students can enter at any time.

Further information may be obtained from the Dean of the *Medical School.*

M. F. NICHOLLS, M.Chir., F.R.C.S.
Dean

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL

540 Beds. *540 Beds.*

(UNIVERSITY OF LONDON),

UNIVERSITY STREET, GOWER STREET, W.C.1.

TELEPHONE—EUSTON 5056 (7 lines).

The WINTER SESSION will commence on Tuesday, October 5th, 1937.

THE SCHOOL IS FOR FINAL STUDIES only

STUDENTS are prepared for the degrees of the Universities of: OXFORD, CAMBRIDGE, LONDON, and DURHAM, and for the Diplomas of other qualifying Bodies.

CLINICAL UNITS in MEDICINE, SURGERY, and OBSTETRIC MEDICINE are now in operation. The whole-time Directors of the Units are concerned with the organisation of the teaching generally, but the honorary staff are responsible for the largest share of the teaching in the wards and out-patient Department of the Hospital. The new Obstetric Hospital is now finished and in full occupation.

Director of the Medical Unit—Prof. T. R. ELLIOTT. Director of the Surgical Unit—Mr. WILFRED TROTTER

Director of the Obstetric Unit—Prof. F. J. BROWNE.

FEES—Inclusive fee to cover complete Clinical Course £45 per annum for three years. Oxford and Cambridge students who have completed their course in Pathology: £40 per annum for three years. There are no extras, as these fees include (i) Courses of Instruction in Pharmacy, Vaccination, and Fevers; (ii) Life Subscription to the Medical Society or Women's Medical Club.

APPOINTMENTS—Forty-seven appointments are open during the year to students, in addition, salaried appointments to the annual value of over £2,000.

SCHOLARSHIPS, EXHIBITIONS, and PRIZES of the value of over £1,000 are awarded annually. Amongst the most important are

I. GOLDSMID ENTRANCE SCHOLARSHIPS entitling the holder to the Final Course of Medical Study, are offered for competition annually in July, and are open to students who are preparing for the Degrees of the Universities of London, Oxford, Cambridge, Durham, or other British Universities, or for the Diplomas of the Royal Colleges of Physicians and Surgeons.

II. GOLDSMID ENTRANCE EXHIBITION (value £80), entitling the holder to a reduction by £80 of the fees due for the Full Course of Final Medical Study.

III. FILLITER ENTRANCE SCHOLARSHIP IN PATHOLOGY (value £52 10s.) entitling the holder to a reduction by £52 10s. of the fees due for the Full Course of Final Medical Study.

FERRIERE SCHOLARSHIP, value £25 awarded annually in April or October.

GRAHAM SCHOLARSHIP, in Pathology, £300 per annum

LESLIE PEARCE GOULD SCHOLARSHIP, awarded every two years, about £260.

RADCLIFFE CROCKER TRAVELLING SCHOLARSHIP in Dermatology awarded every five years, about £280.

MAGRATH SCHOLARSHIP in Clinical Medicine, about £160.

ATCHISON SCHOLARSHIP, about £55 per annum; tenable for two years.

PERCIVAL ALLEYN SCHOLARSHIP, about £300, awarded every three years.

ATKINSON MORLEY SCHOLARSHIP, £45 per annum; tenable for three years.

BILTON POLLARD FELLOWSHIP, of the annual value of £650; tenable for a normal maximum of three years.

ARTHUR POLLARD LOAN FUND, of the approximate annual value of £55

BUCKNILL SCHOLARSHIP entitles the holder to the Intermediate Medical Course at University College, and for the Final Course at the Medical School.

Further information and Prospectus can be obtained from the Secretary, and the Dean can be interviewed at any time by appointment.

Dean—GWYNNE WILLIAMS, M.S., F.R.C.S *Vice-Dean*—W. J. PEARSON, D.S.O., M.C., M.D., F.R.C.P.

Sub-Dean for Dental Students—J. L. DUDLEY BUXTON, L.M.S.S.A., L.D.S., R.C.S.Eng. *Secretary*—R. V. JENKINS.

UNIVERSITY COLLEGE HOSPITAL DENTAL SCHOOL

NATIONAL DENTAL HOSPITAL, GREAT PORTLAND ST., W.1.

LECTURERS.

Dental Surgery and Pathology.—J. L. DUDLEY BUXTON, L.M.S.S.A., L.D.S.R.C.S.
Mondays and Wednesdays at 5 p.m. October to March.

Special Anatomy. — ALAN SHEFFORD, O.B.E., L.D.S.R.C.S.
Tuesdays at 5 p.m. October to March.

Orthodontics.—A. C. McLEOD, D.D.S., B.Sc.(Dent.), L.D.S.
Tuesdays at 5 p.m. May to July.

Dental Mechanics.—J. A. SNAREY WRIGHT, L.D.S.R.C.S.
Wednesdays at 5 p.m. January to March.

Dental Materia Medica.—H. DAVIS, B.Sc., A.I.C., Ph.C.
Tuesday and Fridays at 2 p.m. May to July.

Bacteriology of the Mouth.—Sir KENNETH GOADBY, K.B.E., D.P.H., L.R.C.P., M.R.C.S., L.D.S.R.C.S.
Wednesdays at 2 p.m. January to March.

General Pathology.—Vacant.
Thursdays and Fridays at 4 p.m. January to July.

Bacteriology.—Vacant.
Tuesdays at 2 p.m. January to July.

Dental Histology.—A. K. INCE-JONES, L.R.C.P., M.R.C.S., L.D.S.R.C.S.
Saturdays at 9.30 a.m. January to March.

Dental Metallurgy.—H. TERREY, B.Sc.
Tuesdays at 5 p.m. at University College. October to December.

Anaesthetics.—M. W. P. HUDSON, M.B., B.S., D.A.
Tuesdays at 5 p.m. October to December.

Radiology.—D. A. IMRIE, M.D.Laus., L.R.C.P.E., L.R.C.S.E., D.M.R.E., L.D.S.
Wednesdays at 12 noon. July.

Special Medicine Lectures.—J. C. HAWKSLEY, M.D., M.R.C.P.
Thursdays at 5 p.m. January to July.

Special Surgery Lectures.—A. J. GARDHAM, M.S., F.R.C.S.
Wednesdays at 4 p.m. January to July.

THE WINTER SESSION COMMENCES TUESDAY, OCTOBER 5th, 1937.

This Hospital and School, situated in the centre of a large population, and within a few minutes of University College Hospital, has recently been reorganised and equipped on the highest standard of modern requirements, and admirably adapted for the teaching of students in every branch of the Science and Art of Dental Surgery. The mechanical laboratory, conservation room, and X-rays departments are replete with all the latest approved appliances.

Students (men and women) enter as students of University College Hospital, and attend classes in anatomy and physiology at University College, adjacent to University College Hospital.

Each student serves as a dresser in the extraction, anaesthetic, conservation, and X-rays departments, which provides him with the opportunity of observing and actually carrying out the methods of work in all branches.

Four House Surgeons are appointed half-yearly.

The Calendar, containing full information as to lectures, fees, prizes, etc., may be had on application to the Sub-Dean of Dental Students, who attends the University College Hospital Medical School, University Street, Gower Street, W.C.1, on Wednesdays, at 9.30 a.m.

LONDON HOSPITAL MEDICAL COLLEGE & DENTAL SCHOOL

THE WINTER SESSION will Open on Friday, October 1st.

The LONDON HOSPITAL serves the East End of London, and with eight hundred and fifty beds is the largest voluntary Hospital in England The Out-patient Department, which deals with a hundred thousand new patients per annum, is extensively used for teaching.

The size of the Hospital necessitates a large number of resident medical officers Every year seventy resident house physicians and house surgeons and eighty salaried non-resident clinical assistants are appointed from among recently qualified students The opportunities which these appointments offer for obtaining clinical experience is invaluable

The MEDICAL COLLEGE is attached to the Hospital and is staffed by Professors of Anatomy, Physiology, Bacteriology, Chemical Pathology, Morbid Anatomy and Medicine of the University of London.

SPECIAL COURSES in Anatomy and Physiology for the Primary F.R.C.S. and Advanced Courses in Surgery for the Final F.R.C.S. Examination, and in Medicine for the M.D and M.R.C.P Examinations, are held twice a year

ENTRANCE SCHOLARSHIPS AND PRIZES of the total value of £950 are awarded annually Research Funds to the value of £113,000 permit of assistance being given to students and graduates engaged in medical research

The MEDICAL COLLEGE contains a modern Museum of Pathology and a Library provided with all the current medical periodicals in charge of a full-time librarian There is also an Athenaeum Club and Dining Hall, a Gymnasium, a Fives Court and two Squash Courts in the Students' Hostel. The Athletic Ground of 13 acres at Hale End is within easy distance of the Hospital.

The HOSPITAL is only 20 minutes from Charing Cross and Baker Street Stations For those who wish to live in immediate proximity to the Hospital there is accommodation for sixty students in the Students' Hostel

Further details may be obtained from the Dean, Dr. A. E. CLARK-KENNEDY, M.D., F.R.C.P., Physician to the Hospital and Fellow of Corpus Christi College Cambridge, who is always pleased to meet students wishing to see the Hospital and College, and to whom application for admission should be made, Turner Street London E.1

UNIVERSITY OF LONDON

OPHTHALMIC HOSPITAL MEDICAL SCHOOL

ROYAL LONDON OPHTHALMIC HOSPITAL

(Moorfields Eye Hospital), CITY ROAD, E.C.1.

Qualified Medical Practitioners and Registered Medical Students may enter on the Practice of the Royal London Ophthalmic Hospital (Moorfields) at any time, and are, on certain conditions, eligible for appointment as Chief Clinical Assistant, Clinical Assistant and Junior Assistant.

Courses of Instruction, extending over a period of five months, begin in OCTOBER and MARCH.

1. Practical Refraction Classes.
2. Methods of examination and use of the ophthalmoscope.
3. Lectures every afternoon on the following subjects: (*a*) Anatomy, including Embryology and Normal Histology; (*b*) Physiology; (*c*) Optics, including Physiological Optics; (*d*) Pathology and Bacteriology; (*e*) Ophthalmic Medicine and Surgery, consisting of: Medical Ophthalmology, External Diseases of the Eye, Motor Anomalies and Squint Diseases of the Retina and Optic Nerve, Diseases of the Uveal Tract.
4. Ophthalmoscopic Conditions: a practical class with demonstrations each week at 5 p.m.
5. Occasional Lectures on subjects allied to Ophthalmology.
6. Operative Surgery. In these classes the usual operations are performed by the student upon pigs' eyes.
7. Practical Pathology. A course of demonstrations on the normal and morbid histology of the eye is given by the pathologist in the laboratory.
8. Practical Bacteriology.
9. Classes in Radiography.
10. Physico-therapy (Ultra-violet Light, Diathermy, etc.)
11. Slit-lamp Microscopy.

FEES.—A composition fee of 35 guineas will admit Students once to all the lectures and classes (except the classes of Physico-Therapy, and Slit-lamp Microscopy, and the examination fee).

DIPLOMA IN OPHTHALMIC MEDICINE AND SURGERY AND OTHER DEGREES IN OPHTHALMOLOGY.

The above complete curriculum is specially designed to meet the requirements of candidates entering for these examinations.

Fees for the Practice of the Hospital:

Perpetual	£5 5 0	Two months	£2 2 0
Three to six months	£3 3 0	One month	£1 1 0

Clinica work begins at 9 a.m daily Operations are performed between 10 a.m. and 1 p.m.

For further particulars apply to the Secretary to the Medical School at the Royal London Ophthalmic Hospital, City Road, E.C.1; or to the Dean, Charles Goulden, O.B.E., M.D., M.Chir., F.R.C.S.

GOLDEN SQUARE, THROAT, NOSE AND EAR HOSPITAL

LONDON, W.1

HONORARY MEDICAL STAFF

SURGEONS: Mr. Lione. Colledge, Mr. F. Cunliffe Ormerod; Mr. A. R. Dingley; Mr. Gilbert H. Howells; Mr. J. F. Simpson; Mr. S. A. Beards; Mr. J. C. Hogg.
ASSISTANT SURGEONS: Mr. J Roydon Peacock; Mr. J. P Monkhouse; Mr. Maxwell Ellis; Mr. G. Livingstone
PHYSICIANS: Dr. C. E. Lakin; Dr. N. L. Rusby
NEUROLOGIST: Dr L. R. Yealland.
PATHOLOGIST: Dr. R. B. Hervey-Wyatt.
OPHTHALMOLOGIST: Mr. F. A. Williamson-Noble
GENERAL SURGEON: Mr. J. B. Hunter
DENTAL SURGEON: Mr. Hart.
RADIOLOGIST: Dr. Hope.
ANAESTHETISTS: Dr. G. I. Moriarty; Dr. A. W. Matthew, Dr. S. Coffin; Dr J. H. T. Challis; Dr. F. Longhurst; Dr. D. Lewis; Dr. C. Hochschild; Dr. G. Edwards; Dr Blair Gould, Dr. Broad.

The Hospital has 100 beds for In-patients and an annual Out-patient attendance of over 60,000

CLINICAL INSTRUCTION

Clinical instruction in the Diagnosis and Treatment of Diseases of the Ear, Nose, and Throat is given in the Out-patient Department from 2 to 5 p.m. daily, and on Tuesdays and Thursdays from 6 to 9 p.m. also. Major operations are performed every morning and afternoon except Saturdays, in the In-patient Operating Theatres Minor operations are performed in the Out-patient Operating Theatre on three mornings a week.

Practitioners and Medical Students are admitted to the practice of the Hospital as Post-Graduates. Clinical Assistants whose duty it is to assist the staff, are appointed as vacancies occur.

For further information apply to the Dean: *GILBERT H. HOWELLS.*

THE UNIVERSITY OF LIVERPOOL

FACULTY OF MEDICINE.

THE MEDICAL SCHOOL provides complete courses of instruction for the Examinations of the University of Liverpool, and also meets the requirements of other Universities and Examining Bodies in the United Kingdom.

Other Schools of the Faculty are:—The School of Dental Surgery, the School of Hygiene, the School of Tropical Medicine, and the School of Veterinary Science.

DEGREES AND DIPLOMAS IN THE FACULTY OF MEDICINE.

Bachelor of Medicine & Bachelor of Surgery	M.B., Ch.B.	Doctor of Veterinary Science	D.V.Sc.
Doctor of Medicine	M.D.	Doctorate in Philosophy	Ph.D.
Master of Surgery	Ch.M.	Licence in Dental Surgery	L.D.S.
Master of Orthopaedic Surgery	M.Ch.Orth.	Diploma in Public Health	D.P.H.
Bachelor of Dental Surgery	B.D.S.	Diploma in Tropical Medicine	D.T.M.
Master of Dental Surgery	M.D.S.	Diploma in Tropical Hygiene	D.T.H.
Bachelor of Veterinary Science	B.V.Sc.	Diploma in Veterinary Hygiene	D.V.H.
Master of Veterinary Science	M.V.Sc.	Diploma in Medical Radiology & Electrology	D.M.R.E.

Valuable Fellowships, Scholarships, and Prizes are offered for competition each year.

Clinical Instruction is given at (a) four General Hospitals, viz., The Royal Infirmary, the Royal Southern Hospital, the David Lewis Northern Hospital, and the Stanley Hospital; (b) five Special Hospitals, viz., The Eye, Ear and Throat Infirmary, the Women's Hospital, Liverpool, the Royal Liverpool Children's Hospital, the Liverpool Maternity Hospital, and the St. Paul's Eye Hospital; (c) certain Municipal Hospitals, and the County Mental Hospital, Rainhill.

Prospectuses containing full information may be obtained on application to Professor W. H. Wood, Dean of the Faculty of Medicine, The University of Liverpool.

UNIVERSITY OF MANCHESTER

FACULTY OF MEDICINE

The WINTER SESSION Commences on OCTOBER 7th.

The Laboratories and Museums afford every facility to Students and Graduates for Practical Instruction, as well as for Original Research.

SCOPE OF INSTRUCTION.

Complete Courses of Instruction are offered for the Examinations of the University of Manchester, and also for the Examinations of other Examining Bodies in the United Kingdom. Post-Graduate Courses are held in preparation for the Diploma in Psychological Medicine (Manch.), and the Certificate in Venereal Diseases; Clinical Assistantships are also available at various hospitals. In the Dental Department Complete Courses are given preparing for the Degrees and Diploma in Dentistry granted by the University, as well as for the Diploma of the Royal College of Surgeons of England, and other Dental Diplomas. The Public Health Laboratories are situated at a short distance from the University. The fullest opportunities are offered to Graduates and others in preparation for the Diplomas in Bacteriology, in Public Health and in Veterinary State Medicine. Particulars may be obtained from the Dean of the Medical School.

OPPORTUNITIES FOR CLINICAL STUDY.—ROYAL INFIRMARY AND OTHER HOSPITALS.

The Clinical Instruction is given in the Royal Infirmary, opened in 1909 on a site near to the Medical School. It is provided with every modern requirement for the treatment of the sick and the investigation of disease. Instruction in Special Subjects is given in other Hospitals associated with the University. A large number of beds in the General and in the Special Hospitals are available, thus affording unrivalled opportunities for Clinical Study.

1. Manchester Royal Infirmary	586 beds	8. Hospital for Diseases of the Throat and Chest	160 beds
2. The St. Mary's Hospitals for Women and Children	290 beds	9. Hospital for Diseases of the Skin	54 beds
3. Manchester Children's Hospital	190 beds	10. Christie Cancer Hospital and Holt Radium Institute	104 beds
4. Manchester Royal Eye Hospital	166 beds	11. Ancoats Hospital	150 beds
5. Manchester Northern Hospital for Women & Children	113 beds	12. Salford Royal Hospital	263 beds
6. Fever Hospital for Infectious Diseases	600 beds	13. Dental Hospital of Manchester.	
7. Hospital for Diseases of the Ear	31 beds	14. Manchester Babies' Hospital.	

HOSPITAL APPOINTMENTS.

In consequence of the large number of Hospitals associated with, or in the vicinity of, the University, exceptional opportunities are offered to Graduates to obtain Resident Hospital Appointments.

SCHOLARSHIPS, EXHIBITIONS AND PRIZES.

Two Open Entrance Scholarships for Graduates, each of the value of 160 guineas, are offered yearly in July. In addition, the Dreschfeld Scholarship of £20 per annum, the John Russell Medical Entrance Scholarship of £45 per annum, and other Entrance Scholarships of the value of £30 to £40 a year for two or three years, are also tenable in the Medical Faculty. Fellowships, Scholarships, etc., are also offered for competition to Students of the Faculty.

RESIDENCE FOR UNDERGRADUATES.

There are Halls of Residence both for Men and for Women Students, and lodgings can be recommended. Prospectuses will be forwarded on application to the Registrar.

UNIVERSITY OF BRISTOL

FACULTY OF MEDICINE.

The SESSION commences on October 1st, 1937.

The University grants the degrees of Bachelor of Medicine and Surgery (M.B., Ch.B.), Master of Surgery (Ch.M.), Doctor of Medicine (M.D.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S.), as well as diplomas in Public Health (D.P.H.) (at present in abeyance), and Dental Surgery (L.D.S.), and a Midwife Teacher's Certificate, and provides a Training Course for Health Visitors.

Hospital Practice and Clinical Instruction are provided in the Hospitals and Asylum of the City, associated with the University for this purpose, and students have exceptional opportunities of studying the practice of medicine from a large variety of cases.

Women are admitted to all Classes, Lectures, and Laboratory Practice, and attend them with men. The Halls of Residence for Men and for Women Students are situated near the University.

INCLUSIVE FEES—

For the M.B., Ch.B. curriculum	...	205 guineas
For the B.D.S. curriculum	... ...	215 ,,
For the L.D.S. curriculum	... ...	200 ,,

For additional particulars apply to the DEAN OF THE FACULTY OF MEDICINE.

UNIVERSITY OF DURHAM

THE MEDICAL SCHOOL,

KING'S COLLEGE, NEWCASTLE UPON TYNE

(formerly the University of Durham College of Medicine).

The degrees in Medicine, Surgery, Hygiene, and Dentistry, the Diploma in Public Health, the Diploma in Psychiatry, and the Licence in Dental Surgery of the University of Durham are open to men and women.

The WINTER SESSION, 1937-8, will be commenced on TUESDAY, OCTOBER 5th.

At the Medical School, King's College, Newcastle upon Tyne, students can complete the entire course of professional study required for the above degrees, diplomas, and licence; also for the Examinations of the Royal Colleges of Physicians and Surgeons and other Examining Bodies.

Hospital practice is carried out at the Royal Victoria Infirmary, a general hospital containing more than 700 beds, and there are facilities for the study of the various special subjects General and Special Post-graduate Courses are held.

Practical Midwifery can be studied at the Princess Mary Maternity Hospital, which contains 90 beds, with an annual indoor and outdoor attendance on 3,000 cases. Lectures are given on Psychological Medicine in the Medical School, and clinical instruction at the Mental Hospital, Newcastle. Clinical instruction in Infectious Diseases is given by the Medical Officer of Health in the City Hospital at Walkergate.

The Dental Department includes a dental hospital equipped on the most modern lines, with abundant material for clinical teaching and facilities for training in practical dental mechanics.

Particulars may be obtained from the DEAN, Medical School, Northumberland Road, Newcastle upon Tyne.

THE UNIVERSITY OF SHEFFIELD

Vice-Chancellor: A. W. PICKARD-CAMBRIDGE, D.Litt., LL.D., F.B.A.

FACULTY OF MEDICINE.

Dean: Professor G. A. CLARK, M.D.

The University grants Degrees in Medicine (M.B., Ch.B., M.D., Ch.M.), and in Dental Surgery (B.D.S., M.D.S.). It also grants a Diploma in Dental Surgery (L.D.S.). These are all open to men and women on equal terms.

The session 1937-38 begins on October 6th.

Lectures and laboratory courses are given in the University, whilst clinical instruction is provided in the general and special Hospitals in the City.

Although the teaching is primarily directed towards the requirements of the University the instruction amply covers those of other examining bodies. A number of resident hospital appointments are open to qualified male students of the school.

Halls of Residence.—For Men: Crewe Hall, Clarkehouse Road, Sheffield, 10; Stephenson Hall, Taptonville Road, Sheffield, 10.

For Women: University Hall for Women, Endcliffe Vale Road, Sheffield, 10.

Particulars of the Halls may be obtained from the Wardens.

Scholarships.—A number of Entrance Scholarships are open to students wishing to enter the Faculty of Medicine. There are also post-graduate scholarships.

A prospectus containing all necessary details of the School, and one giving particulars of scholarships, may be obtained free from—W. M. GIBBONS, Registrar.

THE UNIVERSITY OF LEEDS

SCHOOL OF DENTISTRY

The First Term begins on **October 4th, 1937.**

The degrees of B.Ch.D. and M.Ch.D., as well as a diploma, L.D.S., are conferred by the University.

The systematic Classes and Lectures are held in the School of Medicine and School of Dentistry of the University, while the clinical instruction is given in the Leeds General Infirmary and Dental School Hospital. The combined courses of study are arranged to meet the University Regulations in the first instance, but they also afford every opportunity for study to students preparing for the dental examinations of other Licensing Bodies.

Intending students can enter as pupils in the Dental School and can obtain instruction in the preliminary scientific subjects in the Department of Science of the University.

For further particulars application should be made to:—

The Warden, School of Dentistry, Leeds, 1.

THE UNIVERSITY OF LEEDS

FACULTY OF MEDICINE

SCHOOL of MEDICINE and THE GENERAL INFIRMARY at LEEDS

The First Term begins on **October 4th, 1937.**

The degrees of M.B., Ch.B., Ch.M. and M.D. are conferred, and diplomas in Public Health and Psychological Medicine are granted by the University.

The systematic Classes and Lectures are held in the School of Medicine of the University, while the Clinical instruction is given in the General Infirmary. The combined courses of study are arranged to meet the University Regulations in the first instance, but they also afford every opportunity for students preparing for the examinations of any licensing body.

The instruction in the subjects for the First Examination is given in the Department of Science of the University.

The Composition Fee for the Academic Courses and Clinical instruction is £242.

For further particulars application should be made:—

Regarding instruction given at the University to **The Academic Sub-Dean,** School of Medicine, Leeds, 2.

Regarding instruction given at the Infirmary to **The Clinical Sub-Dean,** School of Medicine, Leeds, 2.

BIRMINGHAM SCHOOL OF DENTISTRY.

UNIVERSITY of BIRMINGHAM and BIRMINGHAM DENTAL HOSPITAL.

DEAN OF THE FACULTY OF MEDICINE: STANLEY BARNES, M.D., D.Sc., F.R.C.P.
DEAN OF THE DENTAL HOSPITAL: C. H. HOWKINS, C.B.E., D.S.O., M.R.C.S., L.R.C.P., L.D.S.
PROFESSOR OF DENTAL SURGERY: H. F. HUMPHREYS, K.H.P., O.B.E., M.C., T.D., D.L., M.B., Ch.B., M.D.S., L.D.S.

The Session will commence on MONDAY, OCTOBER 4th, 1937.

DEGREES AND DIPLOMA IN DENTAL SURGERY.

The Degrees of Bachelor of Dental Surgery (B.D.S.) and Master of Dental Surgery (M.D.S.) and the Diploma in Dental Surgery (L.D.S.) are open to Students who follow the requisite courses in the University.

The School of Dentistry, in conjunction with the General and Queen's Hospitals, affords a complete curriculum for the Dental Diplomas and Dental Degrees of the University and all other Licensing Bodies.

The Dental Hospital is fully equipped for the training of students in Mechanical, Prosthetic, and Operative Dentistry.

A DENTAL SCHOLARSHIP of the value of £46 17s. 6d. is offered annually by the University. For syllabus and further information, application should be made to the Dean of the Faculty of Medicine, the University, or to the Dean of the Dental Hospital, Great Charles Street, Birmingham.

UNIVERSITY OF BIRMINGHAM. FACULTY OF MEDICINE.

(Associated with the General, Queen's and Special Hospitals for Clinical Teaching.)

THE NEXT SESSION OPENS ON OCTOBER 4th, 1937.

The University grants Degrees in Medicine, Surgery and State Medicine, and a Diploma in Public Health: also Degrees and a Diploma in Dental Surgery

The Courses of instruction are also adapted to meet the requirements of other Universities and Licensing Bodies.

HOSPITAL APPOINTMENTS.

A large number of Resident Hospital appointments in Birmingham and District are open to qualified students of the School.

SCHOLARSHIPS, EXHIBITIONS AND PRIZES.

Entrance and other Scholarships and Exhibitions and various Prizes and Medals are awarded annually in the Faculty of Medicine, full details of which are in the Faculty syllabus.

SCHOOL OF DENTISTRY.

(University of Birmingham and Birmingham Dental Hospital).

The School of Dentistry, in conjunction with the General and Queen's Hospitals, affords a complete curriculum for the Dental Diplomas and Dental Degrees of the University and all other Licensing Bodies. A Dental Scholarship of the value of £46 17 6, tenable for one year, is offered annually.

PRE-REGISTRATION MEDICAL AND DENTAL EXAMINATIONS.

The necessary courses of Instruction in Chemistry, Physics and Biology may be attended in the University

For syllabus and further information apply to the Registrar

STANLEY BARNES, M.D., D.Sc., F.R.C.P., Dean of the Faculty of Medicine

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

(INCORPORATED 1505).

Copies of Regulations for the Fellowship, Licence, Higher Dental Diploma, and Licence in Dental Surgery, containing Dates of Examinations, may be had on application to DAVID THOMSON, Clerk of the College, Surgeon's Hall, 18, Nicolson Street, Edinburgh.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

The EXAMINATIONS for the LICENCE of the College (as a single qualification) for the ensuing year will be held on the *First Wednesday* and the following days of every month (except September and October).

Candidates for the LICENCE (as a single qualification) must send their names to the Secretary one week before the date of the Examination at which they propose to appear.

The EXAMINATIONS for the MEMBERSHIP of the College are held on the *Second Tuesday* and the following days of *January, April, July,* and *October*.

Candidates for the MEMBERSHIP must submit their applications and testimonials to the Secretary one month before the date at which they wish to appear for Examination.

For the Regulations in regard to the various qualifications granted by the College, and all other information, application may be made to the Secretary.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.
ROYAL COLLEGE OF SURGEONS OF EDINBURGH.
ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

COPIES OF REGULATIONS for the TRIPLE QUALIFICATION (L.R.C.P.E., L.R.C.S.E., and L.R.F.P. and S.G.) and the DIPLOMA IN PUBLIC HEALTH, containing Dates of Professional Examinations for the year 1937-38, Curriculum, &c., may be had on application to THE REGISTRAR, Surgeons' Hall, 18, Nicolson Street, Edinburgh; or to THE REGISTRAR 242, St. Vincent Street, Glasgow

ROYAL (DICK) VETERINARY COLLEGE EDINBURGH

Principal — O. CHARNOCK BRADLEY, M.D., D.Sc., F.R.C.V.S.

115th SESSION COMMENCES OCTOBER.

COURSES OF INSTRUCTION QUALIFY FOR M.R.C.V.S. and B.Sc.(Edin.).

COLLEGE CALENDAR, with full particulars of EXAMINATIONS, BURSARIES, &c., may be obtained from A. C. DOULL, C.A. Secretary.

THE INCORPORATED EDINBURGH DENTAL HOSPITAL AND SCHOOL

The Incorporated Edinburgh Dental Hospital and School, at 30, 31, and 32, Chambers Street, offers special advantages to Dental Students.

The General Courses required for the Dental Diploma are taken in the School of Medicine of the Royal Colleges.

General Hospital Practice and Clinical Instruction in Medicine and Surgery are taken at the Royal Infirmary.

The School of Medicine and the Royal Infirmary are within three minutes' walk of the Dental Hospital.

Dental Hospital Practice, extending over two calendar years, affords the student ample opportunity for a full acquaintance with every branch of dentistry.

Fee for two years' Dental Hospital Practice £26 5s., and Hospital Outfit of Instruments £27 10s.

Women students are welcomed.

The Practice and Lectures of the Hospital are recognized by and qualify for, all the Licensing Boards.

The minimum cost of Professional Education, and the Licence in Dental Surgery of the Royal College of Surgeons of Edinburgh, amounts to approximately £160.*

Students who desire to take a Medical qualification, in addition to the Diploma in Dental Surgery, have admirable facilities for so doing. The Triple Qualification of the Royal Colleges of Physicians and Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow (L.R.C.P. & S.), is recommended. The combined courses are arranged concurrently and should be completed in a minimum time of 5½ years. The minimum cost of Professional Education, Triple Qualification, and Licence in Dental Surgery amounts to approximately £260.*

* Exclusive of premium for Mechanical Instruction (£63) and cost of Hospital Outfit of Instruments.

DEAN—A. C. W. HUTCHINSON, D.D.S., M.D.S., L.D.S., F.R.S.E.

F.R.C.S. (Edin.).

POSTAL and ORAL COURSES.

Full details of above and Private Tuition — H. C. ORPIN, F.R.C.S., Surgeon's Hall, Edinburgh

UNIVERSITY OF ABERDEEN

SESSION, 1937-1938.

FACULTY OF MEDICINE.

The WINTER SESSION commences on TUESDAY, OCTOBER 5th, 1937, and closes on FRIDAY, MARCH 18th, 1938.
The SUMMER SESSION commences on TUESDAY, APRIL 19th, 1938, and closes on FRIDAY, JUNE 24th, 1938.
The Preliminary Examinations will commence on THURSDAY, SEPTEMBER 2nd, 1937, and MONDAY, MARCH 21st, 1938.
The Faculty of Medicine embraces Twelve Chairs, besides various Lectureships, and instruction is given in all departments of Medical Science:—

PROFESSORS.

Biology.—James R. Matthews, M.A., F.L.S., F.R.S.E., and L. Hogben, M.A., D.Sc., F.R.S.
Physics.—John A. Carroll, M.A., Ph.D.
Chemistry.—Alexander Findlay, M.A., D.Sc., Ph.D.
Anatomy.—Alexander Low, M.A., M.D.
Physiology.—E. W. H. Cruickshank, M.D., D.Sc., Ph.D., M.R.C.P., F.R.S.E.
Materia Medica.—David Campbell, M.C., M.A., B.Sc., M.D., F.R.F.P.S.
Pathology.—John S. Young, M.C., M.A., B.Sc., M.D.
Bacteriology.—John Cruickshank, M.D.
Surgery.—James R. Learmonth, Ch.M., F.R.C.S.E.
Medicine.—Leybourne S. P. Davidson, B.A., M.D., M.R.C.P., F.R.C.P.E., F.R.S.E.
Midwifery.—D. Baird, B.Sc., M.D., D.P.H., F.C.O.G.

LECTURERS.

Embryology.—G. Leslie Purser, M.A.
Public Health.—Harry J. Rae, M.C., M.A., M.B., Ch.B., D.P.H.; Douglas Wales Berry, M.C., M.D., D.P.H.
Forensic Medicine.—Robert Richards, M.A., M.D., F.R.C.S.E.
Bio-Chemistry.—Edgar Beard, B.Sc.
Morbid Anatomy.—William M. Davidson, M.B., Ch.B.
Tropical Medicine.—Geo. Alex. Williamson, M.A., M.D., D.P.H., D.T.M.
Experimental Physiology.—William Burns, B.Sc., M.B., Ch.B.
Malignant Disease and Radium Officer.—W. G. Evans, M.B., B.S., M.R.C.S., L.R.C.P.
Medical Ethics.—George Williamson, M.A., M.B., C.M., F.R.C.P.E.

CLINICAL AND SPECIAL TEACHERS.

Royal Infirmary.

Clinical Medicine.—Professor Leybourne S. P. Davidson, B.A., M.D., M.R.C.P., F.R.C.P.E., F.R.S.E.; A. G. Anderson, M.A., M.D., F.R.C.P.; A. W. Hendry, O.B.E., M.D., M.R.C.P.
Clinical Surgery.—Professor J. R. Learmonth, Ch.M., F.R.C.S.E.; Fred. K. Smith, M.A., M.B., Ch.B.; W. Anderson, O.B.E., M.B., Ch.B., F.R.C.S.
Clinical Gynaecology.—D. Baird, B.Sc., M.D., D.P.H., F.C.O.G.
Clinical Midwifery.—George S. Davidson, M.A., M.B., Ch.B., F.R.C.S.E., M.C.O.G.
Ophthalmology.—W. Clark Souter, M.D., D.O.; Harold Edgar Smith, M.A., M.B., Ch.B.
Diseases of Ear, Nose, and Throat.—John H. Otty, M.A., M.B., Ch.B., F.R.C.S.E., D.L.O.
Diseases of the Skin.—Thomas E. Anderson, M.D.
Venereal Diseases.—Frederick J. T. Bowie, M.B., Ch.B., D.P.H.
Radiology and Electro-Therapeutics.—John E. Blewett, M.D., D.M.R.
Dental Surgery.—Hugh M. Crombie, M.B., Ch.B., L.D.S.
Anaesthetics.—J. Ross Mackenzie, M.D.
Clinical Chemistry.—Alexander Lyall, M.A., M.D., M.R.C.P.

Maternity Hospital.

Obstetrics and Antenatal Clinic.—D. Baird, B.Sc., M.D., D.P.H., F.C.O.G.
Maternity and Child Welfare.—James A. Stephen, M.A., M.B., Ch.B.

Ophthalmic Institution.

Ophthalmology.—A. R. Galloway, O.B.E., M.A., M.B., C.M.

Royal Mental Hospital.

Mental Diseases.—R. Dods Brown, M.D., F.R.C.P.E.

Dispensary.

Vaccination.—John Brown, M.B., Ch.B., D.P.H.

City Hospital.

Fevers.—Harry J. Rae, M.C., M.A., M.B., Ch.B., D.P.H.
Tuberculosis.—George S. Banks, M.B., Ch.B., D.P.H.

Royal Hospital for Sick Children.

Diseases of Children.—Alexander Mitchell, M.A., Ch.M.; Wm. Brown, O.B.E., M.B., Ch.B., F.R.C.P.
Anaesthetics.—J. Ross Mackenzie, M.D.

Health Service for Children of School Age.—Alexander F. MacBean, M.A., M.B., Ch.B., D.P.H.

Numerous Bursaries, Scholarships, Fellowships, and Prizes may be held by Students in this Faculty. The total cost of the curriculum for the Degrees of M.B. and Ch.B., including Class, Hospital, Matriculation, and Degree Fees, is approximately £240.

The Degrees in Medicine granted by the University are: Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The degree of Doctor of Philosophy (Ph.D.) is also granted in this Faculty. A Diploma in Public Health (D.P.H.) is granted after a special examination in Public Health to Graduates in Medicine of any University in the United Kingdom.

A Prospectus of the Classes, Fees, &c., may be had on application to the Secretary of the University and full details of the Courses, Degrees, Examinations, Bursaries, Prizes, Fellowships, &c., will be found in the Aberdeen University Calendar published by the Aberdeen University Press, Ltd.

The University also grants Degrees in Arts, Science (Pure, Agriculture, Forestry and Engineering), Law, Divinity, Education and Commerce, particulars of which may be had on application to—

H. J. BUTCHART, Secretary.

SCHOOL OF MEDICINE

OF

THE ROYAL COLLEGES, EDINBURGH

(Founded 1505)

WINTER SESSION, 1937-8. Opens on October 5th.

The Lectures qualify for the English and Scottish Universities and other Medical Examining Boards.

One-half of the Qualifying Classes required for graduation in the University of Edinburgh may be attended in this School.

Early application to the Dean for admission to the School is essential, by March 1st for Summer, and by August 1st for Winter Session.

Calendar, giving particulars of the Classes, Fees, Examinations, etc., sent (price 1s., post free) on application to THE DEAN OF THE SCHOOL, SURGEONS' HALL, EDINBURGH.

UNIVERSITY OF EDINBURGH

Principal—SIR THOMAS H. HOLLAND, K.C.S.I., K.C.I.E.

Prospective students are required to make application for admission on a prescribed form not later than 1st JULY of the year in which they wish to enter.

FACULTY OF MEDICINE.

Dean—Professor SYDNEY SMITH, M.D.

PROFESSORS.

Chemistry—George Barger, M.A., D.Sc., F.R.S
Zoology—J. Ritchie, M.A., D.Sc.
Botany—Sir Wm. Wright Smith, M.A., D. ès Sc.
Anatomy—J. C. Brash, *M.C.*, M.A., B.Sc., M.D
Physiology—I. de Burgh Daly, M.A., M.D.
Materia Medica—A. J. Clark, *M.C.*, M.D., F.R.S.
Pathology—A. Murray Drennan, M.D.
Bacteriology—T. J. Mackie, M.D.
Forensic Medicine—Sydney A. Smith, M.D.
Public Health—P. S. Lelean, C.B., C.M.G., F.R.C.S.
Medicine—W. T. Ritchie, O.B.E., M.D.
Surgery—Sir D. P. D. Wilkie, M.D., Ch.M.
Midwifery and Gynaecology—R. W. Johnstone, C.B.E., M.A., M.D
Clinical Surgery—Sir John Fraser, Ch.M., M.D.
Clinical Medicine—W. T. Ritchie, M.D., D. Murray Lyon, M.D., D.Sc., D. M. Dunlop, M.D.
Tuberculosis—Sir Robert W. Philip, M.A., M.D., LL.D
Therapeutics—D. M. Dunlop, M.D.
Psychiatry—D. K. Henderson, M.D.
Child Life and Health—Charles M'Neil, M.A., M.D.

LECTURERS.

Anatomy—E. B. Jamieson, M.D., R. Walmsley, M.D., R. L. Saunders, M.B
Applied Anatomy—F. E. Jardine, M.B.
Physiology—Philip Eggleton, D.Sc. Dr. Trowell, L. E. Bayliss, B.A., Ph.D., A. Ninian Bruce, M.D., D.Sc., J. D. S. Cameron, M.B
Materia Medica—C. M. Scott, M.B.
Pathology—W. G. Millar, M.B., R. F. Ogilvie, M.D
Pathology of Children—Agnes MacGregor, M.B
Bacteriology—C. P. Beattie, M.B., C. A. Green, M.B., C. G. Anderson B.Sc., Ph.D., C. E. Van Rooyen, M.D.
Physics—G. A. Carse, M.A., D.Sc., J. Paton, M.A., B.Sc.
Botany—J. L. S. Smith, M.A., A. Nelson, B.Sc., Ph.D., J. Anthony, M.A., B.Sc.
Chemistry—Edgar Stedman, B.Sc., Ph.D., C. P. Stewart, M.Sc., Ph.D Ellen Stedman, M.Sc
Zoology—C. H. O'Donoghue, D.Sc., R. A. R. Gresson, Ph.D., P. Gray, Ph.D. G. F. Friend, B.A., B.Sc., J. A. Kitching, Ph.D.
Tropical Diseases—Lt.-Col. E. D. W. Greig, C.I.E., M.D.
Entomology and Parasitology—A. E. Cameron, M.A., D.Sc., D. O. Morgan, Ph.D., J. W. McHardy, B.Sc.
Public Health—John Guy, M.D., J. du P. Langrishe, D.S.O., M.B
Medicine—J. G. McCrie, M.B.
Infectious Diseases—A. Joe, M.D
History of Medicine—J. D. Comrie, M.A., *B.Sc.*, M.D.
Neuropathology—J. H. Biggart, M.D.
Neurological Surgery—N. M. Dott, M.B.
Applied Physiology—W. C. Wilson, M.B.
Clinical Neurology—Edwin Bramwell, M.D.
Venereal Diseases—R. C. L. Batchelor, M.B.
Psychology—J. Drever, M.A., *B.Sc.*, *D.Phil.*
Radiology—R. McWhirter, M.B., D.M.R.E
Psychiatry—R. G. McInnes, M.B., J. R. Bailey, M.B., A. Ninian Bruce D.Sc., M.D., C. M. Ross, M.B.
Therapeutics—A. R. Gilchrist, M.D., W. M. Arnott, M.B.
Orthopaedics—W. A. Cochrane, M.B.
Clinical Midwifery—R. W. Johnstone, M.A., M.D., Douglas Miller, M.D., W. F. T. Haultain, O.B.E., M.C., B.A., M.B., E. C. Fahmy, M.B., John Sturrock, M.B., Clifford Kennedy, M.B., E. M. Robertson, M.B., J. B. Dewar, M.B.
Child Life and Health—L. H. F. Thatcher, M.D., *Gertrude Herzfeld*, M.B., J. M. Murray, M.B., W. C. Wilson, M.B., H. L. Wallace, M.B., D. N. Nicholson, M.B., E. F. Dott, M.B., T. Y. Finlay, M.D.
Clinical Surgery—C. F. W. Illingworth, M.D., B. M. Dick, M.B., D. Band, M.B.
Clinical Medicine—R. M. Murray Lyon, M.D., W. Melville Arnot, M.B., J. A. Bruce, M.B
Obstetrics and Gynaecology—R. T. Thin, M.B.

CLINICAL TEACHING STAFF, ROYAL INFIRMARY.

Clinical Surgery—Geo. L. Chiene, M.B., W. J. Stuart, M.B., J. W. Struthers, M.B., Sir D. P. D. Wilkie, M.D., Ch.M., Henry Wade, M.D., Sir John Fraser, M.D., Ch.M., J. M. Graham, Ch.M., A. Pirie Watson, Ch.M., F. E. Jardine, M.B., W. Q. Wood, M.D., Ch.M. J. J. M. Shaw, M.D., Walter Mercer, M.B., K. Paterson Brown, M.B., R. Leslie Stewart, M.B., T. M'W. Millar, M.B., D. S. Middleton, M.B.
Clinical Medicine—W. T. Ritchie, M.D., John Eason, M.D., D. Murray Lyon, M.D., J. D. Comrie, M.D., Alex. Goodall, M.D., A. Fergus Hewat, M.D., W. D. D. Small, M.D., W. A. Alexander, M.B., D. M. Dunlop, M.D., A. R. Gilchrist, M.D., T. R. R. Todd, M.D., J. K. Slater, M.B., J. D. S. Cameron, M.D., W. R. Russell, M.D., J. G. McCrie, M.B., R. M. Murray Lyon, M.D., W. L. Lamb, M.B
Clinical Gynaecology—R. W. Johnstone, M.D., W. F. T. Haultain, M.B., Douglas Miller, M.D., E. C. Fahmy, M.B., John Sturrock, M.B., *C. D. Kennedy*, M.B
Diseases of the Larynx, Ear and Nose—G. Ewart Martin, M.B., I. S. Hall, M.B., J. P. Stewart, M.D., A. B. Smith, M.D.
Diseases of the Skin—Robert Aitken, M.D., G. H. Percival, M.D., Ph.D., G. A. G. Peterkin, M.B.
Diseases of the Eye—H. M. Traquair, M.D., E. H. Cameron, M.B., C. W. Graham, M.B., J. R. Paterson, M.B.

Practical Instruction is afforded, under the superintendence of the Professors, in Laboratories with the necessary appliances, and in Tutorial and Practical Classes connected with the above Chairs, and opportunities are afforded to Students to extend their practical knowledge and engage in original research.

Opportunities for Hospital Practice are afforded at the Royal Infirmary, the Royal Hospital for Sick Children, Royal Maternity Hospital, the City Fever Hospital, Edinburgh Municipal Hospitals, and the Royal Edinburgh Hospital for Mental Disorders. Upwards of 3,800 beds are available for the Clinical Instruction of Students of the University.

Four Degrees in Medicine and Surgery are conferred by the University of Edinburgh, viz., Bachelor of Medicine (M.B.), *Bachelor of Surgery* (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.)

The Class Fees for M.B. and Ch.B., including Hospital Fee (£12), amount to about £215, and the Matriculation and Examination Fees to £47 15s. 6d. An additional Fee of £21 is payable by those who proceed to M.D., and £21 by those who proceed to Ch.M.

POST-GRADUATE INSTRUCTION.—Courses of instruction are given for the University Diplomas in Public Health, Tropical Medicine and Hygiene, Psychiatry, and Medical Radiology. These Diplomas are open to approved registered practitioners as well as to graduates in Medicine and Surgery of the University. Courses of instruction for the Diploma in Tropical Veterinary Medicine are also given. This Diploma is open to those holding an approved Veterinary qualification registrable by the Royal College of Veterinary Surgeons. *The University also takes part in the Courses given under the auspices of* the Edinburgh Post-Graduate Courses in Medicine. In the departments of the Faculty of Medicine, provision is made for research by students of graduate standing. In the University laboratories facilities will be provided for candidates for the Degree of Ph.D. whose applications to engage in research have been *accepted by the Senatus*.

A Syllabus and further information as to Matriculation, the Curricula of Study for Degrees, etc., may be obtained from the Dean of the Faculty of Medicine; and for Degrees in the Faculties of Arts, Science, Divinity, Law, and Music, from the Deans of these Faculties, or from the Secretary; and full details are given in the University Calendar, published by James Thin, 55, South Bridge, Edinburgh. Price, by post, 5/9.

June, 1937. By authority of the Senatus, W. A. FLEMING, Secretary.

UNIVERSITY OF WALES.

THE WELSH NATIONAL SCHOOL OF MEDICINE.

The Welsh National School of Medicine comprises departments of Materia Medica and Pharmacology; Pathology and Bacteriology; Medicine; Surgery; Obstetrics and Gynaecology; Preventive Medicine and Public Health; Tuberculosis.

COURSES OF INSTRUCTION FOR MEDICAL DEGREES AND DIPLOMAS.

Courses of Instruction are given by the School in the above Departments, for the medical degrees of the University of Wales, and may be attended by students preparing for degrees and diplomas of other Examining Bodies.

The next Session opens on October 5th, 1937.

Hospital Instruction is given at the Cardiff Royal Infirmary, Llandough Hospital, City Lodge Hospital, City Mental Hospital, City Isolation Hospital, The Lord Pontypridd Hospital (Acute Rheumatism—Children), Prince of Wales' Hospital (Orthopaedic), Cefn Mably, Glan Ely and Sully Hospitals (Tuberculosis).

POSTGRADUATE STUDY.

Facilities are given in the School for approved research in all branches of Medicine and Surgery. Postgraduate Scholarships are available, *ranging in value from* £150 to £250 per annum.

Complete Postgraduate Courses of Instruction are given for the Diploma in Public Health, and for the Tuberculous Diseases Diploma of the University of Wales.

Application for admission to any of the Courses should be made, as early as possible, to the Secretary, The Welsh National School of Medicine, The Parade, Cardiff, from whom further particulars may be obtained.

30th June, 1937.

UNIVERSITY OF ST. ANDREWS

Chancellor—The Rt. Hon. The Earl BALDWIN OF BEWDLEY, K.G., P.C., LL.D.
Rector—(Vacant.)
Vice-Chancellor and Principal—SIR JAMES COLQUHOUN IRVINE, C.B.E., Sc.D., D.Sc., LL.D., D.C.L., F.R.S.

The University of St. Andrews includes the United College of St. Salvator and St. Leonard and St. Mary's College in St. Andrews and University College, the Advanced Medical School, and the Dental School in Dundee.

FACULTY OF MEDICINE

Dean and Adviser of Studies at Dundee—PROFESSOR FRANCIS JAMES CHARTERIS, M.D.
Adviser of Studies at St. Andrews—PROFESSOR D. WATERSTON, M.D.

The University confers the following Degrees and Diplomas:—M.B., Ch.B., M.D., Ch.M., Ph.D., D.P.H. (all open to men or women).

Session 1937-38 commences October 5th, 1937. The whole curriculum may be taken at Dundee, or the first two years may be taken in St. Andrews and the remaining three in Dundee.

Clinical Instruction. Ample facilities at Dundee Royal Infirmary (450 beds), Maryfield Hospital (330 beds), King's Cross Hospital (250 beds), Ashludie (120 beds), Dundee Mental Hospital (600 beds), Dundee Eye Institution, Dental Hospital, and other Medical and Surgical Institutions in Dundee.

Hospital Appointments. Numerous resident hospital appointments are available in the above institutions.

Residence Halls: For Men in St. Andrews, for Women in St. Andrews and Dundee. The William Low Residence for Medical Students at Dundee is available for students during Clinical study.

Students' Unions, Athletic Grounds and Gymnasia in St. Andrews and in Dundee.

Bursary (Scholarship) Competitions: For Dundee, entry April 9th; Examinations, May. For St. Andrews, entry May 6th; Examinations, June.

Bursaries Exclusively for Medical Students: At St. Andrews: Taylour-Thomson (for women), 1 of £40 and 1 of £30 for 5 years; Malcolm (for men and women), £40 for 5 years, vacant annually. At Dundee: Hepburn (for men or women), £25 for three years.

Bursaries for which Medical Students are Eligible: At St. Andrews: About 10 Bursaries ranging in value from £50 to £20, tenable for 3, 4 or 5 years, vacant annually, and Fourth year Bursaries of £50, £30 and £22. At Dundee: Nine Entrance Bursaries of from £50 to £40 for four years, and four bursaries of from £30 to £25 for allocation in the remaining years of the course. In addition there are four scholarships of £100 available for graduates.

Residential Entrance Scholarships for Men: At St. Andrews: Seven or eight of £100 competed for annually in June. Medical students are eligible.

Preliminary Examination: September and March. Entries, August 6th and February 6th.

Fees: For complete M.B., Ch.B. Course, exclusive of Examination Fees, Hospital Fees, etc., £182.

Provision for Post-Graduate Study and Research.

Full information may be got from the Secretary of the University, 71, North Street, St. Andrews, or the Dean of the Faculty of Medicine, Westlands, St. Andrews.

SCHOOL OF DENTISTRY

Adviser of Studies: W. GRAHAM CAMPBELL, M.B., C.M., L.D.S., D.D.S.

The University confers the Degrees of B.D.S., M.D.S., and Ph.D. and the Diplomas of L.D.S. and D.P.D.

Full facilities for instruction are available in the Scientific Departments of the University, the Advanced Medical School and Medical and Surgical Institutions.

The Dental Hospital is fully equipped for the training of Students in Mechanical, Prosthetic and Operative Dentistry.

Financial assistance is available for students.

Full information may be obtained from the Adviser of Studies, Dental Hospital, Dundee.

The University, St. Andrews, August, 1937.

QUEEN'S UNIVERSITY OF BELFAST.

FACULTY OF MEDICINE—SESSION 1937-8

Vice-Chancellor: F. W. OGILVIE, M.A.

Anatomy.—T. Walmsley, M.D., C. J. A. Woodside, M.B., F.R.C.S and R. H. Hunter, M.D.
Operative Surgery and Applied Anatomy.—H. P. Malcolm, M.Ch.
Dunville Chair of Physiology.—H. Barcroft, M.A., M.D.
Practice of Medicine.—W. W. D. Thomson, M.D., B.Sc., D.P.H.
Practice of Surgery.—P. T. Crymble, M.B., F.R.C.S.
Materia Medica and Therapeutics.—J. T. Lewis, M.D.
Midwifery and Gynaecology.—C. G. Lowry, M.D., F.R.C.S.I.
Musgrave Chair of Pathology.—J. H. Biggart, M.D., B.Sc.
Medical Jurisprudence.—J. H. Biggart, M.D., B.Sc.
Ophthalmology.—J. R. Wheeler, M.B., F.R.C.S.
Sanitary Science.—W. J. Wilson, B.A., D.Sc., M.D., D.P.H.
Physics.—K. G. Emeleus, M.A., Ph.D.
Zoology.—T. T. Flynn, D.Sc.
Botany.—James Small, D.Sc.
Chemistry.—A. W. Stewart, D.Sc.
Organic Chemistry.—H. Graham, D.Sc.
Biochemistry.—D. C. Harrison, D.Sc., Ph.D., S. Andrews, M.D
Vaccination.—S. R. Armstrong, M.D.
Pharmacology.—E. B. C. Mayrs, M.D., D.P.H.
Bacteriology.—N. C. Graham, M.B.
Psychological Medicine.—N. B. Graham, M.B.

The Lectures of the WINTER SESSION of 1937-8 will commence on Tuesday, October 12. The Summer Medical Classes will commence on April 12, 1938.

The Anatomical rooms are open during the entire day, and Students are aided in their dissections by the Professors of Anatomy and the Demonstrators.

The Examinations for Medical Scholarships at entrance are held in June.

Scholarships will be open for competition at the Professional Examinations in Spring and Summer, 1938.

The Fees for a complete Medical Course (including Hospital Fees) amount to about £230.

HOSPITALS IN BELFAST (recognized by the University of Clinical Instruction).

ROYAL VICTORIA HOSPITAL.Clinical Fees: Winter Session of six months, £7 7s.; Summer Session of three months £4 4s.; Winter and Summer, nine months, £9 9s.; Perpetual Fees, payable in two instalments, £21. Hospital Fee, half a guinea for each Winter or Summer Session.

MATER INFIRMORUM HOSPITAL.—The Clinical Fees are the same as those of the Royal Victoria Hospital.
BELFAST UNION INFIRMARY and CHILDREN'S HOSPITAL.
BELFAST FEVER HOSPITALS (CITY FEVER HOSPITAL, Purdysburn, and UNION FEVER HOSPITAL).
ROYAL MATERNITY HOSPITAL. BELFAST HOSPITAL FOR SICK CHILDREN.
ULSTER HOSPITAL FOR DISEASES OF WOMEN AND CHILDREN, and MIDWIFERY DISPENSARY.
BELFAST OPHTHALMIC HOSPITAL AND EYE AND EAR DISPENSARY.
BEN ULSTER EYE, EAR, AND THROAT HOSPITAL.
SAMARITAN HOSPITAL. FORSTER GREEN HOSPITAL FOR DISEASES OF THE CHEST.
BELFAST HOSPITAL FOR DISEASES OF SKIN. BELFAST DIST. LUNATIC ASYLUM.

The Calendar, containing full information regarding the new Regulations for Courses, Fees, Scholarships, &c., can be had application to the Bursar, Queen's University, Belfast, price 2s.

By Order of the Vice-Chancellor. ANDREW PICKEN, Registrar.

UNIVERSITY COLLEGE, DUBLIN.

MEDICAL SCHOOL.

Session 1937-38.

WINTER SESSION—Lectures commence on OCTOBER 12th.
Introductory Course on OCTOBER 5th.

Professors and Lecturers.

Anatomy.
Professor—Edward Patrick McLoughlin, B.A., M.D., B.Ch., B.A.O.
Physiology.
Professor—James M. O'Connor, B.A., M.D.
Pharmacology and Biochemistry.
Professor—Edward J. Conway, M.B., D.Sc.
Zoology.
Professor—J. Bayley Butler, M.A., M.B., B.Ch., B.A.O.
Botany.
Professor—Joseph Doyle, B.A., D.Sc
Chemistry.
Professor—Thomas J. Nolan, B.A., D.Sc.
Professor of Chemistry as applied to Medicine—Joseph Algar, B.A., D.Sc.
Lecturer—John Keane, M.Sc., Ph.D.
Physics.
Professor—John J. Nolan, M.A., D.Sc.
Professor of Technical Physics—John J. Dowling, M.A., F.Inst.P
Lecturer—Patrick J. Nolan, D.Sc., Ph.D.
Pathology and Bacteriology.
Professor—Thomas T. O'Farrell, M.D., F.R.C.S.I., D.P.H.
Public Health and Bacteriology.
Professor—William D. O'Kelly, B.A., M.D., D.P.H.
Medicine.
Professor of Medicine—Henry F. Moore, M.D., D.Sc.
Professor of Systemic Medicine—James N. Meenan, M.D., B.Ch., B.A.O., D.P.H.
Surgery.
Professor of Surgery—Henry L. Barniville, B.A., M.D., M.Ch.
Professor of Systemic Surgery—Henry S. Meade, M.Ch., F.R.C.S.I.
Midwifery and Gynaecology.
Professor—Robert P. Farnan, M.B., B.Ch., M.A.O.
Lecturer (Obstetrics)—James J. O'Kelly, B.A., M.B., B.Ch., M.A.O
Lecturer (Gynaecology)—Reginald White, F.R.C.S.I.
Materia Medica and Therapeutics.
Professor—Theobald W. T. Dillon, M.B., B.Ch., B.A.O.
Ophthalmology.
Professor—R. Dwyer Joyce, F.R.C.S.I.
Medical Jurisprudence.
Professor—J. McGrath, M.Sc., M.B.
Dental Surgery.
Professor—E. Sheridan, M.D.S., F.R.C.S.I., L.D.S.
Dental Mechanics.
Professor—J. I. Potter, M.D.S., L.D.S.
Orthodontia.
Lecturer—Laurence Flanagan, B.D.S., M.B., B.Ch.

All Scholarship Examinations in Medicine will be held on October 1st.

Introductory Course.—Particular attention is paid to beginners, for whom a special Introductory Course is delivered at the commencement of the Winter Session, beginning on October 5th; it is continued daily for a week.

Regulations for Courses of Study for Degrees and General Regulations containing information as to Scholarships, etc., may be obtained from The Registrar, University College, Dublin.

ROTUNDA HOSPITAL, DUBLIN.

THE HOSPITAL contains 135 beds. Upwards of 3,000 maternity cases and nearly 1,000 gynaecological patients are treated during the year. Besides the Hospital, there is an external Maternity Department with 2,000 cases. The routine for students consists of attendance at the Morning Lectures on Midwifery and Gynaecology, examination of patients in the Gynaecological Department, attendance at operations, and all abnormal labour in the Hospital Wards and conduction of labour cases in the intern and extern departments. Students, both qualified and unqualified, attend the Ante-Natal Clinics, the Infants' Ward and Dispensary. A Bio-Chemist has just been appointed who is carrying out the ZONDEK-ASCHHEIM test for pregnancy, and is prepared to help any Post-Graduates who are keen on doing research work on the material in the Hospital. An X-Ray Plant is used for diagnosis and treatment. Large new ante-natal dispensary has just been completed giving greatly increased facilities for ante-natal and out-patient gynaecological and infant clinics.

Qualified students are given facilities for observing and following the course of all abnormal cases in the Hospital or in the district and, where practical, are allowed to perform some minor obstetric and gynaecological operations and assist at major ones

The Hospital Courses are always going on during the year, and Students can join at any time. The Class is limited, therefore it is advisable to register in advance. Board and residence can be obtained at the Hospital; the living accommodation has been much improved lately. One grass and two hard tennis courts and one standard squash rackets court are available for students living in the residents' Mess. Extra classes in gynaecological diagnosis and operative midwifery are conducted by Assistants to the Master.

Fees, one month, £6 6s.; months other than the first, £4 4s.; three months, £12 12s.; six months, £21.

The L.M. certificate is given to fully-qualified practitioners of Medicine on examination after six months' resident attendance at the Hospital.

Full particulars from A. H. DAVIDSON, M.D., F.C.O.G., Master, Rotunda Hospital.

UNIVERSITY OF DUBLIN

SCHOOL OF PHYSIC.

TRINITY COLLEGE.

THE WINTER SESSION will begin on 1st October, 1937.

All information regarding Courses for the Medical and Dental Degrees, for the Diploma in Public Health, for the Diploma in Gynaecology and Obstetrics, and for the Diploma in Psychological Medicine may be obtained on application to the Registrar of the School of Physic, Trinity College, Dublin.

THE POLYTECHNIC, REGENT STREET, W.1.

DEPARTMENT OF CHEMISTRY & BIOLOGY.

Head of Department:
H. LAMBOURNE, M.A., M.Sc., F.I.C.

DAY COURSE in CHEMISTRY, PHYSICS, and BIOLOGY, and EVENING COURSE in CHEMISTRY and PHYSICS.

For the First Medical and PRE-MEDICAL EXAMINATIONS.

New Session commences:
Day - - September 21st, 1937.
Evening - - September 20th, 1937.

Fee to London Students:
Day - - £9 9s. per term.
Evening - - £2 2s. per term.

Early application should be made to the Director of Education.

THE MEDICAL AND DENTAL DEFENCE UNION OF SCOTLAND, LIMITED.

Secretaries and Registered Office: Millar, Thomson & Dunlop, C.A., 113, St. Vincent Street, Glasgow, C.2.

ANNUAL SUBSCRIPTION £1. *ENTRANCE FEE 10/-*

No entrance fee to those joining within 12 months of obtaining qualification. Benefits include defence of claims for alleged negligence in professional work, including unlimited indemnity and costs, and advice on professional difficulties.

Particulars and forms of application can be obtained from the Secretaries at the above address.

CITY OF LONDON MATERNITY HOSPITAL

(Incorporated by Royal Charter)
CITY ROAD, LONDON, E.C. 1

Midwifery Training School

PRACTITIONERS and MEDICAL STUDENTS admitted to Hospital Practice with operative Midwifery and Obstetrical complications—nearly 2,000 patients annually. Fees £16 16s. per month or £8 8s. per fortnight (inclusive of board-residence).

PUPILS trained as Midwives in accordance with C.M.B. regulations. Reduced fees under Ministry of Health Scheme. Sister-Tutor on Staff. Post-graduate Courses in Analgesia.

'Phone: Clerkenwell 5171

QUEEN CHARLOTTE'S MATERNITY HOSPITAL

MARYLEBONE ROAD, N.W.1

Medical Students and Qualified Practitioners admitted to the Practice of this Hospital. Unusual opportunities are afforded of seeing Obstetrical Complications and Operative Midwifery (about one half of the total admission being primiparous cases). Over 2,700 patients are admitted to the Wards annually, and in the Ante-natal Department there are over 20,000 attendances per annum. Clinical demonstrations are given by the Staff daily.

For rules, fees, etc., apply H. B. STOKES, Secretary-Superintendent.

WESTMINSTER HOSPITAL, Broad Sanctuary, S.W.1.

THE "WANDER" SCHOLARSHIP IN DISEASES OF CHILDREN.

Applications are invited for the office of "WANDER" SCHOLAR (Clinical Pathologist and Registrar to the Children's Department). Salary £250 per annum. Duties to commence October 1st, 1937. Candidates must be registered medical practitioners who have held a resident hospital post and had some experience in pathology or in diseases of children. The office is a whole-time one and is tenable for one year.

Applications (six copies), together with six copies of three recent testimonials, should be submitted to the undersigned (from whom further details regarding the duties of the office can be obtained), not later than Friday, September 17th, 1937

By Order of the House Committee,
CHARLES M. POWER, Secretary.

THE UNIVERSITY OF SHEFFIELD.

FACULTY OF MEDICINE

The Council of the University and the Board of Management of the Royal Hospital, Sheffield, acting conjointly, are about to make an appointment to the post of ASSISTANT PATHOLOGIST to the Hospital and DEMONSTRATOR OF *PATHOLOGY* to the University. The salary offered is £500 per annum. Applications, accompanied by the names of three referees, should be sent on or before September 18th to the undersigned, from whom further details may be obtained.

W. M. GIBBONS,
Registrar.

UNIVERSITY OF BIRMINGHAM.

APPOINTMENT OF LECTURER IN DEPARTMENT OF ANATOMY.

Applications are invited for the post of LECTURER IN ANATOMY (Grade IIb).

Stipend at the rate of £400 per annum. Duties to begin October 1st, 1937.

Three copies of application, with testimonials, must be sent on or before September 14th to the undersigned from whom further particulars may be obtained

C. G BURTON,
Secretary.

The University,
Edmund Street, Birmingham, 3.
August, 1937

JOHN JACOBS,
Secretary, Otago Hospital Board,
July 15th 1937. Dunedin, New Zealand.

COUNTY OF DORSET.

Assistant County Medical Officer and Medical Officer of Health for the Wareham Borough, the Wareham and Purbeck Rural District, and the Swanage Urban District.

The Dorset County Council invite applications for the joint whole-time appointment of ASSISTANT COUNTY MEDICAL OFFICER AND MEDICAL OFFICER OF HEALTH for the Wareham Borough, Wareham and Purbeck Rural District, and Swanage Urban District (population about 25,000).

The salary for the combined appointment will be £800 per annum, together with a travelling allowance of £50 per annum and necessary out-of-pocket expenses according to the scales now in force.

Applicants must be qualified in accordance with Article 8 of the Sanitary Officers (outside London) Regulations, 1935, and hold the Diploma in Public Health or similar qualification.

The candidate appointed will, as regards his duties as Assistant County Medical Officer, act under the direction of the County Medical Officer of Health, and will be required to perform such duties as may be from time to time prescribed. As regards his duties as Medical Officer of Health, he will be subject to the control and direction of the District Councils concerned.

The post will be designated under the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination. He will also be required to reside within the area for which he is Medical Officer of Health and to take up his appointment on January 1st, 1938.

Candidates must apply in their own handwriting on the prescribed form, to be obtained, on receipt of a stamped addressed foolscap envelope, from the undersigned, by whom applications, accompanied by copies of not more than three recent testimonials, must be received not later than Monday, September 20th, 1937.

Canvassing in any form will be a disqualification.

C. P. BRUTTON,
County Offices, Clerk of the County
Dorchester. Council.
August 21st, 1937.

COUNTY BOROUGH OF IPSWICH.

ASSISTANT MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER.

The Council invite applications for a whole-time Assistant Medical Officer of Health and School Medical Officer. Applicants may be of either sex, but must be fully qualified medical practitioners possessing a Diploma in Public Health and be under 40 years of age.

The salary will be at the rate of £600 per annum, rising, subject to satisfactory service, by annual increments of £25 to a maximum of £700.

The Council have adopted the Local Government and Other Officers' Superannuation Act, 1922, and the appointment will be a designated post thereunder as from April 1st next. The successful candidate will be required to pass a medical examination.

The duties will be principally those of a School Medical Officer, but the person appointed will also be required to work in other departments at the discretion of the Medical Officer of Health.

The appointment is determinable by three months' notice from either side.

Forms of application may be obtained from the Medical Officer of Health, Public Health Department, Elm Street, Ipswich, and applications with copies of not more than three recent testimonials must be delivered to the undersigned not later than September 30th, 1937, in an envelope marked "Appointment of Assistant Medical Officer of Health, etc."

Canvassing directly or indirectly will be a disqualification

Town Hall, A. MOFFAT,
Ipswich. *Town Clerk.*
August 24th, 1937.

COUNTY OF KENT.

ASSISTANT TUBERCULOSIS OFFICER (male).

Applications are invited for the above-mentioned whole-time appointment on the staff of the Public Health Department.

The duties will include attendance at dispensaries, clinical supervision of sanatorium beds, and such other work as may be assigned from time to time.

The salary is at the rate of £600 a year, rising, subject to satisfactory service, by annual increments of £25 to a maximum of £750 a year, with subsistence and travelling allowances, according to the county scale.

The post is designated as an established one under the Local Government and Other Officers' Superannuation Act, 1922, and is terminable by three months' notice on either side. The successful candidate will be required to pass a medical examination

Applications, stating age, qualifications and clinical experience, with special reference to practical experience in the diagnosis and treatment of tuberculosis, accompanied by copies of not more than three testimonials, must be received by the County Medical Officer of Health, Sessions House, Maidstone, *not later than* Tuesday, September 7th, 1937. No official form of application will be issued.

W. L. PLATTS,
Clerk of the County Council.
Sessions House, Maidstone
August 23rd, 1937

COUNTY BOROUGH OF MIDDLESBROUGH. HEALTH DEPARTMENT.

HOLGATE MUNICIPAL HOSPITAL.

Applications are invited from Registered Male Medical Practitioners (unmarried) for the post of ASSISTANT RESIDENT MEDICAL OFFICER at the Holgate Municipal Hospital, at a salary of £270 per annum, together with board, residence, and laundry.

The appointment will be for one year. In addition to hospital duties the successful candidate will be required to undertake relief or holiday duty work of other whole-time members of the Corporation's medical staff as required.

The Municipal Hospital contains 329 beds and is a training school for nurses and affords excellent facilities for postgraduate work and experience.

Application, stating age and experience, together with copies of three testimonials, to be sent to the Medical Officer of Health, Municipal Buildings, Middlesbrough, *not later than* September 15th, 1937.

Municipal Buildings. PRESTON KITCHEN,
Middlesbrough. Town Clerk.
August 30th, 1937

ROYAL ARMY MEDICAL CORPS

Applications are invited from medical men for appointment to commissions in the Royal Army Medical Corps.

Candidates will, for the present, be selected for commissions without competitive examination, and will be required to present themselves in London for interview and physical examination on, or about, 21st October, 1937. They must be registered under the Medical Acts, and normally must not be over the age of 28 years.

Successful candidates will, in the first instance, be given short service commissions for five years. During the 4th year of this period they will be given the opportunity of applying for permanent commissions in either the Royal Army Medical Corps or the Indian Medical Service. Those not selected will retire on completion of five years' service with a gratuity of £1,000.

Candidates who are successful will, unless they are seconded to complete a hospital appointment, assemble at the Royal Army Medical College, London, on 1st November, 1937.

Particulars of the Conditions of Service in the Royal Army Medical Corps, pay and allowances, and forms of application, may be obtained on application, either in writing, or personally, to the Assistant Director General, Army Medical Services, The War Office, London, S.W. 1.

HIS MAJESTY'S COLONIAL SERVICE.

COLONIAL MEDICAL SERVICE.

A vacancy exists for an ASSISTANT MEDICAL SUPERINTENDENT at the CENTRAL MENTAL HOSPITAL, TANJONG RAMBUTAN, in the FEDERATED MALAY STATES.

Qualifications.—Candidates must be British subjects of European parentage, under 33 years of age, and must have had at least two years' experience as an Assistant Medical Officer in a County, City, or Borough Mental Hospital in Great Britain or Ireland. Possession of medical qualifications registrable in the United Kingdom and a Diploma in Psychological Medicine is essential.

Salary.—£840 a year, rising by annual increments of £35 to £1,120 a year.

Quarters.—Furnished quarters are provided at a small rental.

Passages.—Free passages will be provided both for an officer and his family on first appointment and when proceeding on or returning from leave.

Terms of Appointment.—The appointment is pensionable, subject to a probationary period of three years in the first instance.

Duties.—The officer will be required to assist the Medical Superintendent in the treatment of patients, maintenance of discipline, etc., in the Mental Hospital. He may be required to give lectures and clinical teaching on mental diseases to students of the College of Medicine, Singapore.

Further particulars and forms of application may be obtained from the *Director of Recruitment (Colonial Service), 2, Richmond Terrace, Whitehall, London, S.W.1.*

BRITISH POSTGRADUATE MEDICAL SCHOOL.

There are THREE VACANCIES for HOUSE SURGEONS in the Surgical Unit, British Postgraduate Medical School, Hammersmith Hospital, Ducane Road, W.12.

The appointments are for six months in the first instance, and the holder may apply for a further period of six months. Salary at the rate of £105 per annum, with board, lodging and laundry. Duties to commence on October 1st, 1937.

Duties are mainly in General Surgery, but one appointment is to the Department of Traumatic and Orthopaedic Surgery. It is desirable that applicants should have held a previous House appointment.

Applications, with copies of testimonials, should be sent to the Dean of the School not later than September 13th, 1937.

HERTFORDSHIRE COUNTY COUNCIL.

PUBLIC ASSISTANCE.
COUNTY INSTITUTION, OSTER HOUSE. ST. ALBANS.

HOUSE SURGEON

Applications are invited for the post of House Surgeon (either sex) at the above Institution, which comprises general medical and surgical wards, with separate Maternity and Children's Units.

Salary will be at the rate of £175 per annum, with an allowance of £3 3s. per week until such time as board and residence can be provided in the Institution. The appointment will be limited to one year, and not renewable. The House Surgeon must, until quarters in the Institution are provided, reside near the Institution at an address to be approved by the Guardians' Committee.

Candidates must be duly qualified and registered.

Applications, stating age, qualifications and experience, with copies of not more than three recent testimonials, should be sent to the Clerk of the St. Albans Guardians' Committee, Oster House, St. Albans (from whom any further details may be obtained), as soon as possible.

Hertford, ELTON LONGMORE,
Herts. Clerk of the County Council.
August 28th, 1937.

COUNTY BOROUGH OF SMETHWICK. ST. CHAD'S HOSPITAL, BIRMINGHAM.

HOUSE SURGEON.

Applications are invited from registered medical practitioners for the appointment of House Surgeon at the Council's Municipal Hospital. The appointment will be for a period of six months, with a salary at the rate of £150 per annum, with the usual emoluments. If the successful candidate is reappointed for a further period of six months, the salary will be at the rate of £200 per annum. St. Chad's Hospital contains 145 beds, and the cases treated include general medical, acute surgical, and maternity patients. It is staffed by the Honorary Consultants of the Birmingham teaching hospitals.

Form of application may be obtained from the Medical Superintendent, St. Chad's Hospital, Hagley Road, Birmingham 16, to whom applications, endorsed "House Surgeon" and accompanied by copies of three recent testimonials, must be delivered not later than first post on September 11th, 1937.

Canvassing, directly or indirectly, will disqualify.

Council House, FRANK CHAPMAN,
Smethwick. Town Clerk.
August 24th, 1937.

GENERAL POST OFFICE.

Headquarters Medical Branch.
(Female Staff.)

There will shortly be two vacancies for ASSISTANT WOMEN MEDICAL OFFICERS in the Headquarters Medical Branch. The appointments will be pensionable and will carry a salary commencing at £500 a year and rising by annual increments of £25 to £700 a year. The rates of salary are liable to review.

Each candidate must be a fully qualified medical practitioner, a natural-born British subject, and the child of a person who is or was at the time of death a British subject. Candidates must also be unmarried or widows. Preference will be given to candidates under 30 who have held one or more hospital appointments. The successful candidates will not be allowed to engage in private practice in addition to their official duties.

Applications, stating qualifications, age, etc., with copies of any recent testimonials, should be sent to the Chief Medical Officer, General Post Office, London, E.C.1, not later than September 20th, 1937.

Political influence should not be sought in support of applications; it would prejudice rather than assist the candidature.

The Female Medical Staff at Headquarters consists of a senior Woman Medical Officer and five Assistant Women Medical Officers. Information as to the duties can be obtained from the Chief Medical Officer.

Candidates may be required to attend for personal interview in London at their own expense.

BUXTON CLINIC FOR RHEUMATISM AND ALLIED DISEASES.

Applications are invited for the appointment of HOUSE PHYSICIAN. Candidates must be fully qualified and registered, and must have had previous hospital experience. The appointment is for six months, but is renewable. Applications, accompanied by three recent testimonials, should be in the Secretary's hands not later than September 18th.

The appointment is to start about October 1st, 1937.

The Clinic has full facilities for physical and hydrological treatment and has its own radiological department. Investigatory work in Biochemistry, Pathology, and Bacteriology is carried on in conjunction with the Devonshire Royal Hospital.

Salary £150-£200 per annum, with board, residence, and laundry.

H. S. Needham, Secretary, The Buxton Clinic Ltd., Buxton, Derbyshire.

INDIAN MEDICAL SERVICE

RECRUITMENT OF EUROPEAN OFFICERS

Applications are invited from Medical Men for Permanent Commissions in His Majesty's Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or of £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

British subjects of pure European descent who are under 32 years of age and who are registered under the Medical Acts in force in Great Britain and Northern Ireland are eligible to apply.

CAREERS.

The Indian Medical Service offers a permanent career with wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after one year's Indian Service to have his name registered for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of Civil Officials and for general medical administrative purposes: to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

RATES OF PAY.

23	"	1350	40	1695
24	"	1500	40	1830
25	"	1500	40	1830

Note.—(1) The rupee is at present stabilized at a rate equivalent to 1s. 6d.
(2) An officer promoted to the rank of Lieut.-Colonel before completion of 20 years' service will receive pay at the rate of Rs. 1200 per mensem (basic) plus £40 per month overseas pay

Extras.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

ANTEDATES IN COMMISSION.

Candidates possessing certain higher medical qualifications or holding the Diploma in Public Health may be granted an antedate in their commissions. Past service in certain hospital appointments may also render candidates eligible for an antedate. Persons holding or about to hold resident posts at recognized hospitals may be seconded in those posts for a period. The maximum period of antedate, secondment, or antedate and secondment combined, admissible under this paragraph, is limited to 18 months.

OUTFIT ALLOWANCE.

Officers on appointment will receive an allowance of £75 towards the cost of outfit.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

LEAVE.

Leave can be taken at reasonable intervals, and adequate rates of leave pay are provided. Extra leave (known as study leave), which may not exceed 12 months in all during an officer's service, may be granted to officers desirous of pursuing special courses of study of a postgraduate nature. During such leave, study allowance, at present fixed at the rate of 12s. a day in the United Kingdom, £1 a day on the Continent of Europe, and £1 10s. a day in the United States of America and Canada is granted to an officer in addition to ordinary rates of leave pay.

PENSIONS.

The rates of pensions are as follows:—	Per annum.
After 17 years' service for pension	£372 0s.
" 18 " " "	£400 0s.
" 19 " " "	£428 0s.
" 20 " " "	£465 0s.
" 21 " " "	£502 0s.
" 22 " " "	£539 10s
" 23 " " "	£576 10s.
" 24 " " "	£614 0s.
" 25 " " "	£651 0s.
" 26 " " "	£697 10s
" 27 " " "	£744 0s.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with free passage to India. The families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges. Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately three months, prior to their embarkation for India on first appointment. Information as to the rates of pay admissible during this period and subsequently up to arrival in India is contained in the memorandum referred to below.

A memorandum giving full details regarding these appointments and forms of application may be obtained from the UNDER-SECRETARY OF STATE FOR INDIA, MILITARY DEPARTMENT, INDIA OFFICE, LONDON, S.W.1. The Selection Committee will meet at the India Office early in October next, and the selected candidates will be required to join a course of instruction commencing about 1st November, prior to sailing for India in February, 1938. Applications should reach the India Office as soon as possible and in no case later than October 2nd.

INDIA OFFICE, SEPTEMBER, 1937.

CITY OF BIRMINGHAM PUBLIC ASSISTANCE COMMITTEE.

ERDINGTON HOUSE.

ASSISTANT RESIDENT MEDICAL OFFICER

The Public Assistance Committee invite applications from fully qualified medical practitioners for appointment as Assistant Resident Medical Officer at Erdington House.

The Institution, which is approved for the purposes of the D P M. has accommodation for upwards of 1,800 inmates and is set apart for the reception of all classes of mental and nervous disorder. The admission rate is 1,500 per annum Parts of the Institution are certified under the provisions of the Mental Deficiency Acts, 1913/1927. There are facilities for research on the pathological and biological side, and the appointment gives opportunities for postgraduate study.

The Officer appointed will be required to assist in the general medical work of the Institution under the supervision of the Senior Medical Officers

Four weeks' leave of absence will be granted to the successful candidate during the term of office.

The appointment will be for a period of twelve months, and the salary attached to the appointment will be at the rate of £300 per annum, together with full residential emoluments (rations, apartments, laundry, and attendance).

The appointment will be subject to one month's notice on either side.

Any further particulars as to the Institution and/or duties may be obtained upon application to the Medical Officer of the Institution, Dr. H. T. Kirkland, to whom applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, should be forwarded so as to reach him not later than 10 a.m. on Wednesday, September 16th, 1937.

Canvassing in any form, oral or written, direct or indirect, will be regarded as a disqualification.

F. H. C. WILTSHIRE,
Town Clerk.

Council House,
Birmingham, 1.
August 26th, 1937.

CHESHIRE COUNTY COUNCIL CLATTERBRIDGE (COUNTY) GENERAL HOSPITAL NEAR BIRKENHEAD

MEDICAL SUPERINTENDENT

Applications are invited from duly qualified male medical practitioners, with experience in the administrative control of a public general hospital, for the post of Medical Superintendent of Clatterbridge (County) General Hospital, which Hospital has been appropriated under the Public Health Acts.

The salary will be £1,000 per annum, plus emoluments valued at £150.

Candidates must not be more than 45 years of age. Applicants must hold one of the higher Medical qualifications.

The Medical Superintendent will be required to reside within easy reach of the hospital. He will be an Assistant Medical Officer on the Staff of the County Medical Officer of Health, and will be responsible to the County Medical Officer of Health, and through him to the Management Committee, for the control of the hospital, and for the supervision of the work of the Medical, Surgical, Nursing and other personnel.

The Hospital, which has accommodation for 291 patients and is to be enlarged to accommodate 400, provides treatment for medical, surgical and maternity cases, and has a staff of one deputy medical superintendent, two resident assistant medical officers, and ten visiting specialists, with a nursing staff of 78

The appointment will be made subject to the Local Government and Other Officers' Superannuation Act, 1922, and is determinable by three calendar months' notice on either side

Canvassing, directly or indirectly, will disqualify the applicant.

Form of application and further particulars relating to this appointment can be obtained from the undersigned, and must be returned to him not later than September 15th, 1937.

IAN MACKAY,

August 27th, 1937.

CITY OF BIRMINGHAM.

PUBLIC HEALTH DEPARTMENT— TUBERCULOSIS SECTION.

APPOINTMENT OF RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited from single registered male Medical Practitioners for the post of ASSISTANT RESIDENT MEDICAL OFFICER in the Tuberculosis Section of the Public Health Department. The successful candidate will be employed both in a Sanatorium and in a Dispensary.

Candidates should have held a resident General Hospital appointment and an appointment in some Institution set apart for the treatment of those suffering from tuberculosis. Experience in the diagnosis and treatment of non-pulmonary forms of tuberculosis is desirable.

The commencing salary will be at the rate of £400 per annum, rising by £25 to £450 per annum, with emoluments valued at £150 per annum.

The officer appointed will be required to refund to the Council all fees, allowances, and emoluments (other than the foregoing) received by him.

The appointment will be subject to the Birmingham Corporation Superannuation Scheme, to the candidate passing a medical examination, to the Birmingham Municipal Officers' Widows' and Orphans' Pensions Scheme (if applicable), and to one month's notice on either side.

Forms of application and a summary of duties may be obtained from, and should be returned with three recent testimonials to, the Chief Clinical Tuberculosis Officer, 151, Gt. Charles Street, Birmingham, 3, not later than September 16th, 1937.

F. H. C. WILTSHIRE,
Town Clerk.

Council House,
Birmingham, 1.

SURREY COUNTY COUNCIL.

ASSISTANT MEDICAL OFFICER

Applications are invited for the appointment of two Assistant Medical Officers (either sex) Applicants must possess a qualification in Public Health, and have had experience in the Medical Inspection of School Children, in Maternity and Child Welfare, and in the examination and certification of mentally defective children The officers appointed will be required to undertake such other Public Health duties as may be allocated to them. They will be on the staff of the County Medical Officer of Health, must reside in the County of Surrey, and devote their whole time to the work. Salary £600 per annum, rising by annual increments of £20 to £700 per annum. Travelling expenses in accordance with the Council's scale will be allowed.

The appointments will be subject to the approval of the Ministry of Health and of the Board of Education to the successful candidates passing a medical examination, to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and to the Staffing Regulations of the Council, which provide, *inter alia*, that appointments may be determined at any time by three months' notice

Applications, stating age, qualifications, and experience, together with copies of three recent testimonials, should be made on the prescribed form and sent to the County Medical Officer of Health, County Hall, Kingston-upon-Thames, from whom copies of the application form may be obtained, and to whom any inquiries relating to the appointment should be addressed.

Last day for receipt of applications, Wednesday, September 8th, 1937.

Canvassing, directly or indirectly, will disqualify.

DUDLEY AUKLAND,
Clerk of the County Council.

County Hall,
Kingston-upon-Thames.
August 21st, 1937.

LEIGH JOINT HOSPITAL BOARD

Applications are invited from Medical Men (under 45 years of age) for appointment as MEDICAL SUPERINTENDENT of the BOARD'S INFECTIOUS DISEASES HOSPITAL, situate at Astley.

The salary assigned to the office is at the rate of £800 per annum, together with the usual residential allowances.

He will be required to reside in the residence provided (unfurnished) by the Board.

The post is designated under the Local Government and Other Officers' Superannuation Act, 1922, and the emoluments for the purpose of the Act are valued at £150.

Preference will be given to applicants who have held resident medical appointments, since qualification, at an Infectious Diseases Hospital and are experienced bacteriologists

The appointment will be terminable by one month's notice on either side.

Forms of application may be obtained from, and must be returned when duly completed to, the undersigned by noon on Thursday, September 16th, next.

Canvassing, either directly or indirectly, will disqualify.

ERNEST WILLIAMS.
Clerk to the Board.

The Sanatorium,
Astley, Nr. Manchester.
August 22nd, 1937.

WORCESTERSHIRE COUNTY COUNCIL.

ASSISTANT TUBERCULOSIS OFFICER (MALE).

The above-mentioned Council are about to appoint a whole-time Assistant Tuberculosis Officer and applications are now invited for this post.

Applicants must be registered Medical Practitioners between the ages of 25 and 45 years. Special experience and qualifications in Tuberculosis will be necessary, as work under the County Tuberculosis Scheme will form the chief part of the Officer's duties. He should have (1) at least three years' experience in the practice of his profession, (2) spent in general clinical work a period of not less than eighteen months, of which not less than six months have been spent in a Hospital as Resident Officer in charge of beds occupied by general medical or surgical cases, and (3) received special training, for a period of not less than six months, in the diagnosis and treatment of Tuberculosis and in Artificial Pneumothorax treatment. A Diploma in Public Health is desirable. The officer who is appointed will work under the supervision of the Chief Tuberculosis Officer.

The person appointed will be required to reside in the southern half of the County.

The salary will be £600, rising by £25 per annum to £700, with an allowance of £140 per annum for use of his own motor car The engagement will be subject to three months' notice on either side. The post is designated under the Local Government and Other Officers' Superannuation Act, 1922, and a medical examination will have to be passed by the successful candidate.

Applications (on forms to be obtained from the County Medical Officer, County Buildings, Worcester), accompanied by not more than three recent testimonials, must be received by 15th day of September, 1937, addressed to the County Medical Officer, County Buildings, Worcester.

Canvassing disqualifies, and neither the names of the members of the County Council nor of the Committee will be supplied

(*Signed*) C. H. BIRD,
Clerk of the County Council.

Shirehall, Worcester.
August 21st, 1937. (J. 133.)

COUNTY BOROUGH OF BLACKBURN

PUBLIC ASSISTANCE DEPARTMENT

Applications are invited from Medical Practitioners (male) for the appointment of a RESIDENT JUNIOR ASSISTANT MEDICAL OFFICER at QUEEN'S PARK HOSPITAL and INSTITUTION.

The Staff consists of a Resident Medical Officer, a Resident Assistant Medical Officer, a Consulting Surgeon, a Laboratory Assistant, and an X-Ray Attendant.

There is a separate Infirmary, a separate Mental Block, and a separate Sanatorium for Children, and there is opportunity for experience in all departments, including Medical, Surgical, and Midwifery cases. An X-Ray apparatus is installed.

The person appointed will be required to devote his whole time to the duties and also to act as may be directed by the Resident Medical Officer.

The appointment will be limited to a term not exceeding one year

Salary for the first six months at the rate of £150 per annum, and thereafter at the rate of £200 per annum, together with board, apartments, and attendance.

Applications, stating age, qualifications, and experience, accompanied by COPIES of not more than three recent testimonials, must be sent so as to reach the Public Assistance Officer, Public Assistance Offices, Cardwell Place, Blackburn, not later than 10 a.m. on September 8th, 1937.

CHAS S. ROBINSON,
Town Clerk

Town Hall, Blackburn,
August 20th, 1937.

THE ROYAL EASTERN COUNTIES INSTITUTION

for the Mentally Defective, Colchester.

ASSISTANT MEDICAL OFFICER (Male)

Applications are invited for the above post, from unmarried male Medical Practitioners not over 36 years of age Total beds over 1,700.

The medical man appointed will be stationed at the new Extension, Turner Village, and will be required gradually to assume responsibility for administrative work connected with that extension, which has at present over 400 beds. For that reason the commencing salary has been fixed at £400 per annum, together with furnished apartments, board laundry, and attendance. No deductions Previous specialisation in Mental Deficiency is not essential

A Research Department, with a Medical Director and other Staff, working under the Medical Research Council and the Rockefeller Foundation, is attached to the Institution. New Laboratories costing nearly £5,000 will be ready for occupation in October and there is every facility for research work.

Apply before September 8th, giving age, nationality, full details of qualifications, and copies of testimonials, to the Medical Superintendent, Royal Institution, Colchester.

LONDON COUNTY COUNCIL.

PUBLIC HEALTH DEPARTMENT.

Applications are invited for two vacant positions of PART-TIME OBSTETRICIAN AND GYNAECOLOGIST. *Appointments will be to the hospital service of the Council*, but in the first instance one of the appointed officers will be allocated to DULWICH and ST. GILES' (Camberwell) Hospitals and the *other to* ST. MARY, ISLINGTON, ARCHWAY (Highgate) and HIGHGATE Hospitals. Remuneration £600 a year and £600 a year respectively. Each officer will be responsible, *subject to the general administrative supervision* and control of the *medical superintendents*, for the whole of the obstetric and gynaecological work at the hospitals *to which he is attached* (there are no maternity beds at Archway and Highgate Hospitals). Each officer will be required to live within a reasonable distance of these hospitals and to visit them daily and as required (weekly and as *required* in the case of Archway and Highgate Hospitals).

Application forms containing further particulars (stamped addressed envelope *necessary*) from the Medical Officer of Health (S.D.6), County Hall, Westminster Bridge, S.E.1. Forms returnable by September 24th. Canvassing disqualifies.

LONDON COUNTY COUNCIL.

Applications invited from Medical Practitioners with appropriate qualifications for the appointment of ASSISTANT PATHOLOGIST in the Council's pathological service. Salary £650–£25–£800.

For appointments in the Group Laboratories candidates should have special experience in one or more branches of *pathology* in relation to the *diagnosis* and *treatment of disease*.

For the appointment at the Central Histological Laboratory advanced experience *in morbid histology* and *post-mortem* work is *essential*.

Forms of application and further particulars (stamped addressed foolscap envelope necessary) from Medical Officer of Health (Staff Division 2), County Hall, Westminster Bridge, S.E.1, returnable by September 24th, 1937.

Canvassing disqualifies.

LONDON COUNTY COUNCIL. INFECTIOUS HOSPITALS.

Applications invited from medical practitioners for appointment as ASSISTANT MEDICAL OFFICERS (Grades I and II) at various *hospitals* for infectious diseases. Salaries are:—Grade I, £350–£25–£425 a year; Grade II, £250 a year, both inclusive of board, lodging *and* washing. Candidates for Grade I positions should have had experience *in* a resident appointment in a general hospital, and must have had fever experience. Appointment as assistant medical officers, Grade II, are for one year *only* in first instance (renewable *for* a second year under certain conditions), but officers are eligible for *promotion* to Grade I after a minimum period of six months' service.

Application forms obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health (Staff Division 2), County Hall, S.E.1, returnable by September 15th. Canvassing disqualifies.

THE KING EDWARD VII WELSH NATIONAL MEMORIAL ASSOCIATION.

Applications are *invited from duly* registered medical practitioners for the posts of ASSISTANT RESIDENT MEDICAL OFFICER (male, single—*one year appointment*) at the following institutions:

(a) North Wales Sanatorium (247 beds for female pulmonary and male, female, and children non-pulmonary cases), Denbigh, North Wales.

(b) Glan Ely Hospital (196 beds for pulmonary and surgical tuberculosis in men, women, and children), Fairwater, near Cardiff.

Salary £200 per annum, *plus* maintenance.

Applications stating age, qualifications, experience, etc., together with copies of three recent testimonials, should reach the undersigned not later than Wednesday, September 15th, 1937.

D. A. POWELL,
Memorial Offices, Principal Medical Officer.
Westgate Street, Cardiff.
August 30th, 1937.

VICTORIA HOSPITAL, BURNLEY. (150 Beds.)

HOUSE SURGEON (male).

Applications are invited for the above post, which will become vacant on September 30th next. The appointment is for six months in the first instance, at a salary of £150 per annum, together with board, residence and laundry. At the end of this period, reappointment may be arranged for, and, if confirmed, the salary for the second six months will be at the rate of £200 per annum. Applications, with full details of qualifications and experience, and stating nationality, together with copies of recent testimonials, should be addressed to the undersigned forthwith.

J. L. WHEATCROFT,
Secretary.

CHESHIRE COUNTY COUNCIL.

CLATTERBRIDGE (COUNTY) GENERAL HOSPITAL, NEAR BIRKENHEAD. (300 Beds.)

JUNIOR RESIDENT ASSISTANT MEDICAL OFFICER.

Applications (male or female) are invited for the above appointment, *which falls* vacant on October 1st.

The appointment is for a period of six months at a salary of £200 per annum, together with the usual residential allowances.

The appointment may be renewed for a further period of six months.

There is a Non-Resident Medical Superintendent, a Resident Deputy Medical Superintendent, and a *Consulting Staff from Teaching Hospitals*.

Applications to be made on forms obtainable from the undersigned, and returned not later than September 15th, 1937.

24, Nicholas Street, IAN MACKAY,
Chester. County Medical Officer of Health.

WOOLWICH AND DISTRICT WAR MEMORIAL HOSPITAL,
Shooters Hill, London, S.E.18.

General Hospital—112 Beds.

RESIDENT SURGICAL OFFICER.

The Board of Management invites applications from suitably qualified male candidates for appointment as RESIDENT SURGICAL OFFICER. Applicants must have special knowledge of surgery. This appointment (which is recognized by the Royal College of Surgeons of England for the six months' training required of candidates before admission to the Final Examination for the Fellowship) will be for twelve months, with effect from October 1st, 1937, at a salary of £175 per annum plus board, residence, and laundry, and subject to extension for a further twelve months at £200 per annum if approved by the Board of Management.

The closing date for the receipt of applications, which should be made on the prescribed form (obtainable from the undersigned), is September 18th, 1937, and short-listed candidates will be required to meet the Appointments Committee on Thursday, September 23rd, 1937, at 4.45 p.m.

R. S. G. HUTCHINGS,
Secretary.

WEST LONDON HOSPITAL,
Hammersmith, W.6. (239 Beds.)

Required one HOUSE PHYSICIAN, one HOUSE SURGEON, and one HOUSE SURGEON (with Throat, Nose, and Ear duties). The duties of the House Physician include some work in the Children's Department, one House Surgeon will have some work in the Genito-Urinary Department, and the House Surgeon (with T., N., and E. duties) will also act as Resident Casualty Officer. These three appointments (males) are tenable for six months from October 1st next, subject to one month's notice on either side. Salary at the rate of £100 per annum, with board, lodgings, and laundry allowance. Candidates must be registered under the Medical Act.

Applications (which must be made on the printed forms obtained from me) must reach me not later than the first post on Thursday, September 16th. Selected candidates will be required to call upon such members of the medical staff as directed, to be in attendance at the Medical Council Meeting on Friday, September 24th, at 4.30 p.m., and the House Committee Meeting, at 5 p.m., the same day, when the appointments will be made.

H. A. MADGE,
Secretary.

WEST LONDON HOSPITAL,
Hammersmith Road, W.6 (239 Beds.)

Required, one RESIDENT ANAESTHETIST (male). The appointment is tenable until March 31st, 1938, subject to one month's notice on either side. Salary at the rate of £100 a year, with board, lodging, and laundry allowance.

Candidates must be registered under the Medical Act. Applications (which must be made on printed forms obtained from me) must reach me not later than first post on Thursday, September 16th. Selected candidates will be required to call upon such members of the Medical Staff as directed; to be in attendance at the Medical Council Meeting on Friday, September 24th, at 4.30 p.m., and the House Committee Meeting, at 5 p.m., the same day, when the appointment will be made.

H. A. MADGE,
Secretary.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL,
Gray's Inn Road, W.C.1.

RESIDENT HOUSE SURGEON (MALE).

There will be a vacancy for a THIRD RESIDENT HOUSE SURGEON to enter on duty on October 1st, 1937. The appointment will be for a period of nine months: three months as Third House Surgeon, three months as Second House Surgeon, and three months as First House Surgeon. Remuneration at the rate of £75 per annum.

Applications, accompanied by copies of not more than three testimonials, should be sent to the undersigned as soon as possible.

JOHN H. YOUNG,
Secretary-Superintendent.

ELIZABETH GARRETT ANDERSON HOSPITAL, EUSTON ROAD, N.W.1.

Applications are invited from qualified women for the resident post of THIRD HOUSE SURGEON.

The appointment is for four months, with a possible extension for a further six months. Duties to begin October 1st, 1937. Salary at the rate of £50 per annum, with board, residence, and laundry. Further particulars can be obtained from the undersigned, to whom applications with copies of three testimonials should be sent on or before September 17th.

JEAN R. MURRAY,
Secretary.

THE HOSPITAL FOR SICK CHILDREN,
Great Ormond Street, London, W.C.1.

Applications are invited for the post of RESIDENT SURGICAL OFFICER, which becomes vacant on November 1st, 1937. Salary £200 per annum.

The appointment is tenable in the first instance for one year, but may be held for a period of two years, subject to annual re-election.

Candidates must be unmarried, possess a legal qualification to practise, and must have held a responsible hospital appointment at a general hospital.

Applications must be received by noon on Monday, September 27th, 1937, and candidates must be prepared to attend for interview at the hospital on Wednesday, October 6th, 1937, at 4.45 p.m.

Full details of the appointment and forms of application are obtainable from the undersigned.

HERBERT F. RUTHERFORD,
August, 1937 Secretary.

THE HOSPITAL FOR SICK CHILDREN,
Great Ormond Street, London, W.C.1.

A RESIDENT HOUSE PHYSICIAN (male) and a RESIDENT HOUSE SURGEON (male) are required. *Duties to commence on October 18th, 1937.*

The appointments are tenable for six months. Salaries at the rate of £100 per annum.

Candidates must be unmarried, possess a legal qualification to practise, and have held a responsible appointment at a general hospital.

Applications must be received by noon on Monday, September 27th, 1937, and candidates must be prepared to attend for interview by the Joint Committee, at 4.45 p.m. on Wednesday, October 6th, 1937.

Further particulars and forms of application are obtainable from the undersigned.

HERBERT F. RUTHERFORD,
August, 1937. Secretary.

THE PRINCESS BEATRICE HOSPITAL,
EARL'S COURT, LONDON, S.W.5.
(General Hospital, 81 Beds.)

HOUSE PHYSICIAN AND CASUALTY OFFICER (male or female) required for a period of six months as from October 1st, 1937; also CASUALTY OFFICER AND OBSTETRIC HOUSE SURGEON (male or female) required for a period of six months as from October 1st, 1937.

The following details apply to both posts. Salary at the rate of £110 per annum, with board, residence, and laundry (together with £10 to cover all duties during the six months relating to private patients). Previous residence experience desirable but not essential. Full particulars may be obtained from the Secretary-Manager, by whom applications, with copies of three recent testimonials, should be received not later than 9 a.m., September 14th, 1937.

THE PRINCESS BEATRICE HOSPITAL,
EARL'S COURT, LONDON, S.W.5.
(General Hospital, 81 Beds.)

RESIDENT SURGICAL OFFICER (male) required for a period of six months in the first place from October 1st, 1937, eligible for re-election. Salary at the rate of £200 per annum, with board, residence, and laundry (together with £25 to cover all duties during the six months relating to Private Patients). Previous resident experience and F.R.C.S. essential.

Full particulars may be obtained from the Secretary-Manager, by whom applications, with copies of three recent testimonials, should be received not later than 9 a.m., September 14th, 1937.

THE PRINCESS BEATRICE HOSPITAL,
EARL'S COURT, LONDON, S.W.5.
(General Hospital, 81 Beds.)

Applications are invited for the post of HONORARY ASSISTANT OBSTETRIC PHYSICIAN AND GYNAECOLOGIST to the above hospital. Applicants must be Fellows of the Royal College of Surgeons of England. THE WILLESDEN GENERAL HOSPITAL,
Harlesden Road, N.W.10.

Applications are invited from fully qualified and registered candidates (unmarried) for the appointment of a Resident Officer, to hold the appointment of CASUALTY OFFICER for a period of three months from October 1st, 1937, followed by a six months' appointment as HOUSE PHYSICIAN (total nine months).

Salary at the rate of £100 per annum.

Applications to be received by the Secretary not later than first post on Tuesday, September 14th, 1937.

August 25th, 1937.

ST. PETER'S HOSPITAL FOR STONE, ETC.,
Henrietta Street, Covent Garden, W.C.2.

The Office of HOUSE SURGEON will fall vacant on October 1st, 1937, and applications are invited from male candidates with previous experience in a similar office at a General Hospital. The salary offered is at the rate of £75 per annum, with board, lodging, and laundry.

At the expiration of six months' term of office, and subject to the recommendation of the Medical Committee, the House Surgeon is appointed Resident Surgical Officer for a further similar period. Candidates should therefore be prepared, if successful, to remain at the Hospital for twelve months in all.

Applications, accompanied by copies of testimonials, should be forwarded to reach the undersigned not later than the first post on Tuesday, September 7th, 1937.

BOLINGBROKE HOSPITAL, WANDSWORTH COMMON, S.W.11.
(135 Beds.)

Applications are invited for the post of RESIDENT SURGICAL OFFICER (male, unmarried).

The post is that of Senior Resident Officer, and the work being chiefly surgical preference will be given to candidates holding the F.R.C.S. qualification.

The appointment is for twelve months commencing on October 1st, 1937.

Salary £200 per annum, with board, residence, and laundry.

Applications, stating age, qualifications, and experience, with copies of not more than three testimonials, should be sent to the undersigned on or before September 8th, 1937.

W. S. RANDOLPH BISS,
Secretary-Superintendent

THE ROYAL CANCER HOSPITAL (FREE)
(Incorporated under Royal Charter),
Fulham Road, London, S.W.3.

Applications are invited for the post of ASSISTANT RADIUM THERAPIST (full-time).

Applicants must be registered medical practitioners, who hold a Diploma in Radiology.

The appointment will be for one year (subject to renewal) commencing October 1st, 1937, at a salary at the rate of £500 per annum.

Applications, to be made on a form which will be supplied by the Secretary, together with copies only of three recent testimonials, should be sent to the Secretary not later than the first post Monday, September 13th, 1937.

CLEMENT COBBOLD, Secretary.

CENTRAL LONDON OPHTHALMIC HOSPITAL.
Judd Street, St. Pancras, W.C.1.

There is a vacancy for a PATHOLOGIST. Candidates must be duly registered Medical Practitioners and must be willing to attend the Hospital on three afternoons each week. The appointment is for one year (subject to re-election) and carries with it an Honorarium of £105 per annum.

Applications, with copies of not more than four testimonials, must reach the Secretary of the Hospital not later than September 11th.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Judd Street, St. Pancras, W.C.1.

Applications are invited for the post of ASSISTANT SURGEON. Candidates must be Fellows of the Royal College of Surgeons (England) or hold the degree of M.S. (London) in Ophthalmology, and must have held a post as Clinical Assistant for two years at least at a recognized Ophthalmic Hospital.

Applications, with copies of not more than four testimonials, must reach the Secretary of the Hospital not later than September 11th.

THE SALVATION ARMY.
The Mothers' Hospital, Lower Clapton Road, Clapton, E.5.

Applications are invited [illegible] an HONORARY [illegible] MOTHERS' HOSPITAL, members of the Royal College of Physicians and engaged in Consulting Practice.

Details of the appointment may be obtained from the Secretary-Superintendent, to whom 12 copies of the application, with three recent testimonials, should be sent by September 30th, 1937.

EDGAR DIBDEN,
Secretary-Superintendent

CITY OF LONDON MATERNITY HOSPITAL, CITY ROAD, E.C.1.

Applications are invited for the post of MALE ASSISTANT RESIDENT OFFICER for three months from October 1st. At the end of the period the candidate will, if satisfactory, be appointed Senior for three months at £100 p.a.

Forms of application, returnable not later than September 11th, may be obtained from the Secretary.

NORTHAMPTON GENERAL HOSPITAL.
(293 Beds.)

There will be vacancies on October 1st for the following eight appointments:

SENIOR RESIDENT MEDICAL OFFICER. The appointment will be in the first instance for a period of twelve months at a salary of £250 per annum. The successful candidate will be expected to combine certain supervisory duties with the clinical work of one of the posts advertised below, and applicants should state which of these posts is desired. Candidates must have held a responsible resident post, but administrative capacity is more important than outstanding clinical ability.

1. HOUSE PHYSICIAN.
2, 3, and 4. HOUSE SURGEONS (three appointments).
5. HOUSE SURGEON to the Maternity and Gynaecological Department.
6. HOUSE SURGEON to the Ear, Nose and Throat Department.
7 and 8. CASUALTY OFFICERS. First and Second.

Salaries (with the exception of the Senior Resident Medical Officer) will be at the rate of £150 per annum, with board, residence and laundry. Candidates, who must be duly qualified and registered, must be males and of British nationality.

The successful candidates (with the exception of the Senior Resident Medical Officer) will be elected for a period of six months and will be eligible for re-election for a further period of six months.

Applications, stating age, qualifications, etc., with copies of three testimonials, must reach the undersigned not later than the first post on Wednesday, September 8th, 1937.

S. C. W. DISNEY,
August 23rd, 1937. Secretary-Superintendent.

ROYAL DEVON AND EXETER HOSPITAL, EXETER. (260 Beds.)

HOUSE SURGEON (Male).

Applications are invited for this post, which becomes vacant on October 1st.

The appointment is for six months, but candidates are eligible for re-election.

Salary at the rate of £150 per annum, with board, lodging and washing.

Applications, giving particulars as to age and qualifications, together with copies of three recent testimonials, should be sent to the undersigned on or before Tuesday, September 7th.

S. S. COLE,
Secretary and Manager.
August 20th, 1937.

ANCOATS HOSPITAL, MANCHESTER, 4.

This Hospital is recognized by the Royal College of Surgeons for its Surgical Practice.

HOUSE SURGEONS (General) required. To commence duty on October 1st. Two vacancies. Appointment for six months. Salary £100 per annum, with board, residence, laundry, etc.

Applications, stating age, qualifications, previous experience and full particulars, to be forwarded to the undersigned on or before September 8th, together with copies of three recent testimonials.

By Order of the Board,

The post of THIRD RESIDENT will fall vacant on October 1st, 1937, and applications are invited from male candidates, who must be duly qualified Medical Practitioners and unmarried. Salary at the rate of £150 per annum, with board, lodging, and laundry.

At the expiration of six months' term of office and subject to the recommendation of the Medical Board the Third Resident is appointed Second Resident (salary £175 per annum) and then Senior Resident (salary £250 per annum) for similar periods. Candidates should therefore be prepared, if successful, to remain at the hospital for eighteen months in all.

Applications, stating age and qualifications, accompanied by copies of three recent testimonials, should be sent in not later than first post on Tuesday, September 14th. Chosen candidates will be interviewed on Friday, September 17th.

By Order,
HENRY L. EOOT,
Superintendent and Secretary.
September 1st, 1937.

PEMBROKE COUNTY WAR MEMORIAL HOSPITAL,
Haverfordwest, Pembrokeshire.
(64 Beds, to be increased to 100 Beds.)

Rent of consulting rooms, £26 p.a. A suitable residence could be obtained. Good scope, much building going on. Premium £1,200 (contents of consulting rooms, including X-ray plant and electrical apparatus, about £130).

32 LONDON, S.E.—PRACTICE of about £500 p.a. Panel 533. House with surgery accommodation to rent. Premium one year's purchase, or offer.

33 W. OF ENGLAND.—Country PRACTICE doing about £1,400 p.a., in picturesquely situated village. Panel over 600. Good stone-built slate roof house (4 bedrooms, dressing-room, etc.), garage and charming garden, about ¾ acre, for sale. Hunting, fishing, shooting. Premium £2,800.

34 LONDON, W.2.—Old-established PRACTICE in residential district. Receipts last year, £1,440. Panel 1,000, about. Good house to rent at £130 p.a. Premium two years' purchase.

35 MID-DEVON.—Increasing Country PRACTICE, about £800 a year, in delightful part. Appointments and panel return over £350 p.a. Excellent house (6 bedrooms, dressing-room, etc.), in 1¼ acres of grounds. Separate surgery accommodation. Electric light and main water. Garage and stabling. Freehold for sale. Scope. Premium £1,200.

36 DEATH VACANCY.—SOUTH WALES.—Panel and Contract PRACTICE returning about £1,550 p.a. Large compact residence (6 bedrooms), in excellent condition, with two garages and pleasure and kitchen gardens, to rent.

37 COUNTY TOWN, within 65 miles of London.—PARTNERSHIP in Practice averaging between £2,300 and £2,400 p.a. Panel about 2,000. House containing 6 bedrooms, for sale or rent. One-third share (after preliminary Assistantship) at one and three-quarter years' purchase, or near offer.

38 LONDON, E.15.—Old-established PRACTICE averaging £1,670 p.a., in populous suburban district. Panel 1,990. Small house in excellent repair. Rent £50 p.a. Good scope. Premium two and a quarter years' purchase.

39 S. MIDLANDS.—PARTNERSHIP (short preliminary Assistantship) in Practice, over £5,000 p.a., in first-rate town. Panel nearly 5,000. House with 4 bedrooms, garage and garden, to rent. One-fifth share at first at two years' purchase.

40 LONDON, S.E.—Old-established and increasing PRACTICE of £2,500 p.a. in suburban district. Panel 2,000. Detached double-fronted house (5 bedrooms, etc.), garage and garden. Freehold for sale. Premium two years' purchase.

41 S. MIDLANDS.—Old-established PRACTICE of over £1,000 p.a. in beautiful country district on Bucks and Northants borders. Panel 536. Attractive house (6 bedrooms, etc.), Freehold for sale, or rent. Premium two years' purchase.

42 S. OF ENGLAND.—PRACTICE of about £300 p.a. carried on by a medical woman in a cathedral town. Panel 100. House (2 bedrooms, etc.), to rent. Premium £500.

43 AUSTRALIA.—Old-established PRACTICE of £1,400 p.a., in agricultural township. Good house (3 bedrooms, etc.), for sale. Premium £1,600 and £250 for X-ray plant.

44 MIDLANDS.—Old-established PRACTICE in beautiful country district. Cash Receipts last year £1,280, including appointments worth about £60, and a panel between 650 and 700. Visits 2/6 to £1 1s. without medicine. Nicely situated house (4 bedrooms, dressing-room, etc.), with nice garden and two garages. Rent about £80 p.a. Premium two years' purchase.

45 N. WALES BORDER.—PARTNERSHIP (with early succession) in old-established County Practice, about £2,500 p.a., in important town. No panel. Surgery premises could be purchased or rented. The private residence is available if required. A share up to one-half would be sold at first with early succession. Premium two years' purchase.

46 DEATH VACANCY.—ESSEX SUBURB.—Receipts average nearly £850 p.a. Panel 423. Semi-detached house (4 bedrooms). Price £800 freehold. Reasonable offer accepted.

47 LONDON, S.W.1.—SPECIAL PRACTICE for catarrhal conditions, nasal catarrh, hay fever, asthma, etc., etc., about £1,000 p.a., in commanding position in Grosvenor Place. Consultations 1-3 guineas. Special terms for series of [illegible] accommodation to rent at £100 p.a., [illegible]. Scope. Premium one and a-half years' purchase.

48 SEASIDE TOWN WITHIN AN HOUR OF LONDON.—Very old-established PRACTICE. Receipts average £625 p.a. Panel about 300. Nice detached house (5 bedrooms), with garage and garden, for sale or rent. Good scope. Premium £1,000.

Purchasers can raise additional capital for the purchase of approved practices or shares.
Particulars will be forwarded on application.

BOVRIL MEDICAL AGENCY, LTD.

ALDINE HOUSE,
10-13, BEDFORD STREET, STRAND, LONDON, W.C.2.
Telegrams: BOVMEDICAL, LESQUARE, LONDON. Telephone: TEMPLE BAR 1616 (3 Lines).
Chairman and Managing Director, Dr. J. FIELD HALL.

The maximum commission payable on the sale of any Practice or Partnership in Great Britain placed exclusively in the hands of this Agency is £50 (fifty pounds), which sum covers goodwill, drugs, surgery fittings, fixtures and furniture, instruments and book debts, but not house property. Schedule of Terms will be forwarded on application.

Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.
No charge is made to Principals for the introduction of Locum Tenens or Assistants.

1. SURGICAL OPENING.—MIDLANDS COUNTRY TOWN.—A share representing about £1,500 p.a., is offered in an exceptionally sound PRACTICE, owing to the retirement of one of five partners. Total receipts about £9,000 p.a. Panel over 3,500 patients. Fees from 3/- upwards. The ingoing partner, who can choose his own residence, must be able to undertake major surgery. Premium 2 years' purchase.
2. LONDON.—Outlying Northern Suburb.—PARTNERSHIP—A one-third share is available in a rapidly expanding Practice. Receipts for past three years are approximately £1,924-£2,900 and £3,550. Panel of 2,354 patients. Fees 2/6 and 3/6—visits 3/6 upwards. Midwifery about 40/50 cases per annum, minimum 4½ guineas. Considerable scope for further increase. Ingoing partner must be well experienced and have held Hospital appointments, be interested in medicine and children, and, in addition, be a good anaesthetist. Short preliminary assistantship.
3. LANCS.—High-class Seaside and Residential Town.—Easily worked old-established PRACTICE for sale. Gross cash receipts about £1,100 p.a., including a panel of about 325 patients. Fees 3/6 to 10/6. Visits 5/- to 21/-. Midwifery about 12 cases p.a. Minimum 5 guineas rising to 15 guineas. Mostly non-dispensing. Low expenses. Suitable house available with consulting and waiting rooms, 2 reception, 3 bedrooms and a maid's room and box room. Large garden and garage. Leasehold for sale or would be rented. Premium 1¾ years' purchase. There is stated to be good scope for increase for an energetic man.
4. CENTRAL LONDON.—Better-class PRACTICE averaging about £500 p.a., for past 3 years, starting from practically nil 4 years ago. Panel 280, increasing. Ground-floor flat of 7 rooms and 2 bathrooms on rental. Unavoidably neglected. Scope for increase. Premium £550.
5. SUSSEX.—ATTRACTIVE COUNTRY DISTRICT NEAR SEA.—PARTNERSHIP.—A one-fourth share is offered (after a preliminary assistantship) in an old-established and expanding Practice. Gross cash receipts for 1936 were about £3,300 and for the past 8¾ months approximately £2,700. Panel of 1,300 patients. Appointments worth over £300 p.a. Maisonette available or Senior partner might build new house. Premium 2 years' purchase.
6. ESSEX.—PARTNERSHIP offering surgical prospects after short preliminary assistantship.—ONE FOURTH SHARE to commence in well established practice averaging about £5,000 p.a. Panel of 2,300 patients. Suitable house, with 5 bedrooms, etc., can be rented at £60 p.a. Premium 1¼ years' purchase.
7. OPHTHALMIC PRACTICE for sale in a capital Australian City.—Gross cash receipts approximately £2,000 (Australian). Good consulting rooms can be rented at £180 p.a. Further details on application.
8. PHYSIO-THERAPEUTIC PRACTICE with scope for *X*-ray work in large town. ONE HALF SHARE available. Receipts over £2,000 p.a.
9. WEST END PRACTICE.—Death Vacancy—Skins—Genito-Urinary—V.D., Electro-Therapy, etc. Gross cash receipts for past 12 months about £1,815. Fees 2 and 3 guineas. Suitable accommodation available. Premium by arrangement.
10. NORTH-WEST COAST.—Well-established PRACTICE, with seaside town and country work, producing £1,299, including panel and appointments worth about £400 p.a. Suitable house with 3 bedrooms, etc., garden, garage. Rent £50 p.a. Sport of all kinds. Premium only £1,250 for quick sale.
11. NORTH-EAST COAST.—Well-established non-panel PRACTICE, averaging about £800 p.a., but capable of extension as considerable building is in progress. Very good house, with 6 bedrooms, etc. Price £1,500. Premium 1¼ years' purchase.
12. SOUTH COAST.—PARTNERSHIP.—A ONE-HALF SHARE in good middle and upper-class practice producing about £2,550 p.a. Panel of 1,300. Fees 3/6 to 21/-. Suitable house can be rented at £65 p.a. Easily worked, and scope for increase. Premium 2 years' purchase.
13. NORFOLK AND SUFFOLK BORDERS.—A TWO-FIFTHS SHARE, with increase to one-half, is offered in an old-established practice with considerable scope for increase. Receipts approximately £3,300, with panel of about 1,400. Low expenses. Good house available.
14. DEVON COUNTRY.—Old-established PRACTICE producing about £800 p.a. including about £310 from panel of 428 patients. Freehold house for disposal containing 2 reception rooms, lounge hall, 6 bedrooms, waiting room, consulting room, etc., 1¼ acres of garden, garage for 2 cars and stabling. Freehold £2,600. Premium £1,200.
15. LANCS.—Suburb of large town. PRACTICE producing about £800 p.a. with panel of 467 patients. Suitable house on rental at £90 p.a. inclusive, Stated to be scope for increase. Premium £1,100.
16. LONDON, S.E. 11.—Old-established working class PRACTICE producing approximately £500 p.a.. Panel of about 500 patients. Can be worked as lock-up. Premium 1 year's purchase or any reasonable offer accepted.
17. YORKS.—LARGE TOWN.—Well-established better working-class PRACTICE. Receipts for last 12 months about £1,176 with Panel of 1,150 patients approximately. Fees, minimum 2/6 with visits from 3/6 to 7/6. Freehold house for disposal at £900 containing 3 bedrooms, 2 living rooms, surgery, waiting room, etc. Vendor wishes to specialise.
18. SURREY.—PLEASANT TOWN.—PRACTICE produced for past 12 months about £1,280 with a Panel of 800 patients. Fees 3/6 upwards, with visits from 5/- upwards. Midwifery 3 to 10 gns., about 15 cases per annum. Vendor has to give up owing to ill-health. Premium £2,000.
19. EASTERN COUNTY AND MARKET TOWN.—HALF-SHARE PARTNERSHIP in Practice established some 100 years owing to retiral of junior partner. Average cash receipts over £2,400 p.a., of which over £700 comes from Panel and P.A.C. Suitable house available on rental. Ingoing partner should not be more than 30, preferably have a degree and some hospital experience.
20. ASSISTANTSHIP—with a view to a PARTNERSHIP SHARE to produce about £1,100 p.a., in a well-established Practice. Ingoing man must be young, have had considerable hospital experience, and preferably held an Ophthalmic H.S. He should be married or engaged, and a Protestant. Will applicants please give full details of experience, etc.
21. DEVON, SOUTH COAST—A well-established good-class entirely private PRACTICE producing for the past 12 months about £1,000. Panel could be had if desired. Fees 2/6, 3/6, 5/- and 7/6, with a few visits up to 21/-. Non-dispensing. Suitable house containing consulting room, 2 reception rooms, 6 bedrooms, for sale. Freehold £1,400. Partnership introduction. Would be suitable for ex-I.M.S. or similar.
22. DEVELOPING NORTHERN SUBURB.—A 3/8TH SHARE is offered in a well-established and growing Practice. Receipts for 12 months to 1/4/37 amounted to about £5,200, including about £80 from appointments and a Panel of some 5,300 patients. There is a choice of houses available.
23. LANCS.—SUBURB OF LARGE TOWN.—PRACTICE established for 10 years—gross cash receipts for year ended 31/3/37 amounted to about £800, with an increasing Panel of some 470 patients. Fees 2/6 and 3/6, with visits 3/6 and 5/-. Suitable house with good accommodation and separate surgery available on lease at £60 p.a. Premium £1,100, plus good debts, drugs and surgery equipment at valuation. Vendor giving up owing to ill-health.
24. WEST COAST.—Well-established PRACTICE producing about £1,900 p.a., including Panel of 1,450 patients which gives £820 p.a. and one or two small appointments. Visits 3/6 to 12/6. Consultations 3/6, medicine extra. There is a Cottage Hospital, purchaser would get on the staff. There is stated to be scope for surgery. Suitable house on rental at £50 p.a., with rates of £26 p.a. Accommodation is ample, and consists of waiting and consulting room, dispensary with separate entrance, 2 reception, 7 bedrooms and billiard room, half-acre of garden and garage for 2 cars. Premium 1¼ years' purchase.
25. LONDON, E.2.—Lock-up PRACTICE established 80 years for disposal. Income about £800-£900 p.a., with Panel of about 1,150 patients. Fees 2/6 and 3/6. Visits from 3/6. Suitable accommodation available consisting of consulting room, dispensary, waiting room, the remainder being sub-let for £280 p.a. Rent and rates £230 p.a. Premium 2 years' purchase to include about £150 fittings, fixtures, drugs, etc.
26. CITY PRACTICE.—Lock-up, hours 10-1 and 5.30-6.30, producing about £1,000 p.a., including £200 from Panel and appointments. Suitable accommodation available.
27. BAYSWATER.—PRACTICE, established some 65 years for disposal. Gross receipts about £1,440 p.a., with 1,000 Panel patients. Suitable house on lease at £130 p.a. Premium 2 years' purchase.
28. SURGICAL OPENING.—WITHIN 50 MILES OF LONDON.—A £1,000 share is offered to a FIFTH PARTNER in an old-established Practice. The patients comprise all classes and there is little visiting done under 10/6. Ingoing partner would do all surgery, but must be prepared to do ordinary G.P. as well. Choice of houses. Applicants must be 28-40, preferably hold a degree and must have their English Fellowship. Premium 2 years' purchase.
29. LONDON, S.W.—Old-established PRACTICE producing £1,500 p.a., with panel of 1,266 patients for disposal. Appointment and small club bring in about £85 p.a. House available contains Professional accommodation, reception room and 3 bedrooms and maids' room, bathroom. For sale or might be rented. Premium £3,000.
30. NORTH-WEST COAST.—SEASIDE TOWN.—CONSULTING PRACTICE FOR A PHYSICIAN.—Established by vendor (who now wishes to come to London) 4 years ago. Receipts for last year stated to be £1,320 Minimum fee 2 gns. Suitable rooms available at inclusive rental of £64 p.a. Purchaser can choose his own residence and should hold the M.D. or M.R.C.P. Premium 1¼ years' purchase on actual receipts for first year.
31. HAMPSHIRE.—COUNTRY PRACTICE.—Old-established PRACTICE held by vendor for past 7 years. Gross cash receipts stated to average £740 p.a. Panel of 472. Appointments worth about £130 p.a. Fees 3/6 upwards. Pleasant house containing 2 reception, 5 bedrooms, etc., Professional accommodation. Good garden and garage. Rent £55 p.a. Prem. £1,250.
32. LONDON, SOUTH-EAST.—Middle-class PRACTICE held by vendor nearly 30 years, averaging over £700 p.a. Panel of 576 and one appointment worth £25 p.a. Roomy house with good garden and garage. Leasehold for sale.
33. SUSSEX.—VILLAGE PRACTICE NEAR COAST.—Well-established PRACTICE producing about £800 p.a., and capable of increase, attractively situated within five miles of favourite seaside resort. Very nice house, with ¾ acre of garden, in excellent repair. Price for Practice and house, £3,100 or house might be rented for a short period.
34. LONDON.—WESTERN SUBURB.—Old-established private PRACTICE producing about £1,100 p.a. for disposal. There is stated to be good scope for a young man who will undertake panel and midwifery. Fees 3/6 to 10/6. Small compact house on rental. Premium £1,800.
35. SOUTH-COAST SEAPORT.—Long-established PRACTICE for disposal owing to Vendor's retirement. He has held it for the past 39 years. Income last year approximately £573 with a Panel of about 460 patients. Vendor previously held a public appointment producing £450 p.a., which he relinquished owing to age limit. It is considered that anyone devoting whole time to the Practice would increase the receipts. Suitable accommodation available on rental.
36. EASTERN COUNTIES.—Mixed-class PRACTICE in pleasant agricultural district producing for last twelve months over £1,300 p.a. Fees 3/6 to 21/-. Nice house in good position with 2 reception, 4 bedrooms, dressing room, etc. Separate professional accommodation. Modern conveniences. Garden, garage. Price for freehold £1,300. Sport of all kinds and schools within reach.
37. EAST ANGLIA—WITHIN REACH OF TWO GOOD TOWNS.—Old-established, unopposed country PRACTICE averaging over £1,000 p.a., including Panel producing over £450 a year. Low expenses. Detached house in own grounds, containing 2 sitting rooms, 5 bedrooms, etc. Rent £70 a year. Premium £1,750.
38. LONDON—NORTH-WEST.—Recently established and steadily developing PRACTICE producing for last 12 months approximately £1,000, and increasing at the rate of about £200 p.a. Suitable house can be rented or flat obtainable. Premium 2 years' purchase.
39. NORTH-EAST COAST.—Old-established PRACTICE producing about £900 p.a., but stated to be capable of considerable increase. Choice of house. Partnership introduction given, as vendor retiring.

The Agency has made arrangements for special facilities, on very favourable terms, to be afforded to approved purchasers for the advance of part of the premium for any suitable practice or partnership. Full details on application

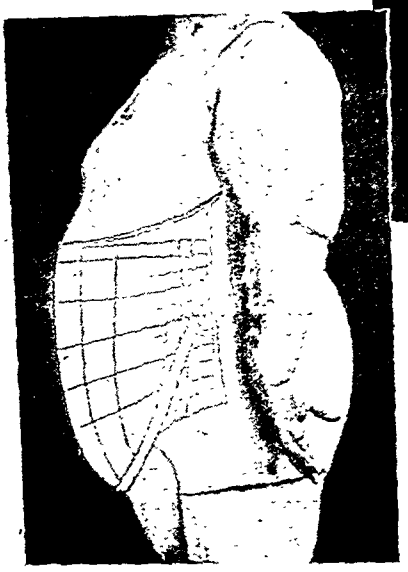
FOR HERNIA CASES WHERE SUPPORT IS NEEDED

A Spencer Support Provides Real Comfort

It will assist in the control of reducible Hernia and in restoring the patient to reasonably normal activity . . .



To be effective a support for hernia must stay in place securely and must be comfortable in order to obtain the patient's full co-operation.

. . . That is why each Spencer Support is individually designed to meet the specific needs of the patient. . . . This ensures satisfactory fit and comfort, and assures that secure "anchorage" of the garment to the figure necessary to prevent it from riding or slipping out of place when the patient is standing, moving or sitting.

Doctors have found Spencer Hernia Supports to be useful in assisting in the control of inoperable cases, and for all other hernia cases, where support is needed. Some doctors prescribe them as a prophylactic measure, especially the Spencer Post-Operative Support designed to offer minimum interference with the natural restoration of the tone of abdominal muscles.

Photograph of a woman with inoperable hernia weighing seventy-five pounds. Same woman (at left) wearing a Spencer.

Photograph of the same woman, pictured above, the hernia effectively controlled and her personal appearance improved.

Spencer Supports for Hernia, like all other Spencers, are liked by patients because they are light in weight, comfortable, flexible, easily laundered and, particularly, because they greatly improve appearance. Spencers have no hard rubber, or heavy metal parts. Yet they are strong, well made, durable—and provide maximum security for the patient. With each Spencer there is a written guarantee that it will NEVER lose its shape.

Trained Spencer Corsetières are resident throughout the Kingdom. Name of nearest gladly supplied on request.
A scientifically trained Spencer Corsetiere will call at your surgery or at your patient's home to take measurements under your supervision.
Spencer Supports and Corsets are never sold in shops.

SPENCER

TRADE REJUVENO MARK PATENTED

FOUNDATION GARMENTS AND SURGICAL SUPPORTS

"We create a design especially for you."

BEWARE OF SUBSTITUTION.—Spencer Corsets Ltd. regret the necessity of warning the medical profession that in several instances where doctors have specifically prescribed a Spencer Support, a corset of another make has been substituted, and because its makers do not understand the Spencer principles of individual designing, has been unsatisfactory. Every genuine Spencer Support bears the SPENCER Label.

ERGOAPIOL (SMITH)

AMENORRHEA - DYSMENORRHEA
MENORRHAGIA - MENOPAUSE

Today, as for years, Ergoapiol (Smith) is the accepted medicament in combating those menstrual anomalies which may be traced to constitutional disturbances; atonicity of the reproductive organs; inflammatory conditions of the uterus or its appendages; mental emotion or exposure to the elements.

The physician readily can ascertain whether his prescription for Ergoapiol (Smith) has been correctly filled by dividing the capsule at the seam, thus revealing the initials M.H.S. embossed on the *inner* surface, as shown in photographic enlargement.

Literature on request.

OVALTINE

IN NUTRITIONAL CRISES

WHILE the average adult is able to maintain a healthy existence on the ordinary everyday diet, there are certain periods in the life of each individual when an increased demand for the vital food elements arises. Outstanding examples are the period of adolescence, the pregnant and nursing states and the stage of convalescence after severe and lowering illnesses.

"Ovaltine" is an eminently satisfactory adjunct to the ordinary dietary at all such times. Composed of fresh, full-cream milk, eggs and malt extract in proportions adjusted to meet physiological requirements, it provides, in an agreeable form, calcium, phosphorus, vitamins and other important food elements.

"Ovaltine" is a metabolic stimulant and digestive which assists the assimilation of other foods and promotes general good health. It can, therefore, be taken regularly with advantage in place of tea, coffee, or other beverages. A noteworthy feature is its delightful taste which is appreciated by people of all ages

A liberal supply for clinical trial sent free on request.

Modern Iron Therapy

Iron 'Jelloids' are an elegant and reliable means of administering the protocarbonate of iron. The preparation has none of the disadvantages of Pil. Blaud. The iron content remains fresh and unoxidized indefinitely, and injury to the teeth is avoided.

The 'Jelloids' are highly effective in the treatment of achlorhydric anaemia and indeed in all the simple anaemias in which massive iron therapy is indicated.

Iron Jelloids

You are cordially invited to apply for samples for clinical test.
The Iron 'Jelloid' Co. Ltd., King George's Avenue, Watford, Herts.

PROGESTIN B.D.H.

The uterine hypersensitivity which results from a deficiency of corpus luteum secretion is, in many cases, the cause of dysmenorrhœa and, in pregnancy, of threatened abortion. Rational treatment consists, therefore, in the administration of Gonan, the gonadotropic-like substance from pregnancy urine, to stimulate the patient's own luteal secretion. In addition, palliative treatment may be necessary, particularly in cases of threatened abortion. Such treatment should always include the administration of Progestin B.D.H. The immediate uterine sedative effect is thus obtained; abortion in many cases will be averted and pain relieved in dysmenorrhœa unless this latter condition is due to uterine hypoplasia.

Butesin Picrate Ointment (Abbott) provides a complete local treatment *always ready for use* on burns of any kind and degree—Steam, electrical, hot metal, sunburn, or for scalds. Time is never lost with sprays, wet dressings or elaborate preparations. ● Combining the powerful anæsthetic and analgesic properties of butesin with the anti-septic qualities of picric acid, Butesin Picrate Ointment quickly brings about the disappearance of intense pain. (Even in very severe burns, relief usually follows within fifteen to twenty minutes.) The preparation fixes and protects denuded areas against infection from without and inhibits any existing infection. No hard crust is formed over the burn and epithelisation after granulation is encouraged. ● Because of these advantages, Butesin Picrate Ointment has many other practical, every-day uses—For application to ulcers, lacerations, abrasions, hæmorrhoids and all other injuries for which an analgesic, antiseptic ointment is indicated. ● Butesin Picrate Ointment (Abbott) is supplied in 1-ounce and 2-ounce collapsible tubes, and in 16-ounce and 5-pound jars. Comprehensive literature and a clinical sample will be sent upon request. The coupon below is for your convenience.

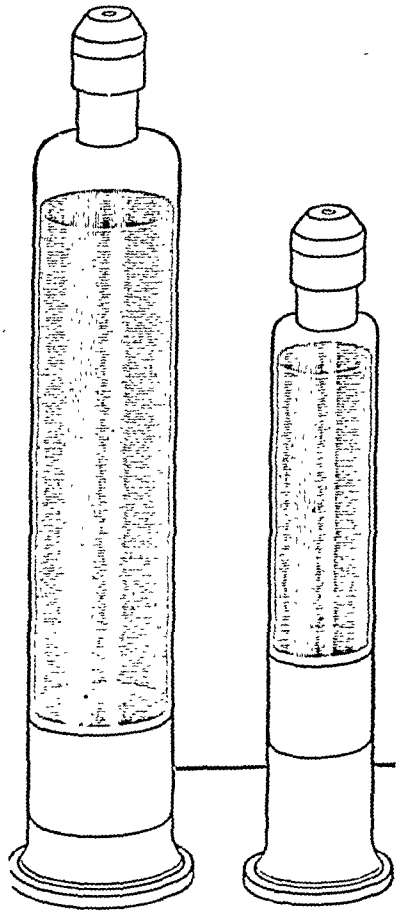
STREPTOCOCCUS ANTITOXIN (SCARLATINA)

GLOBULIN Lederle MODIFIED

WE collected the experience on 306 patients in 18 hospitals and found, as we expected, that our Globulin-Modified process of refinement had cut in half the percentage of reactions. The percentage of *severe* reactions was only 2%!

We also found in our hands new evidence of the efficacy of antitoxin in heading off sequelae, if administered *early*.



Irrespective of the apparent severity of the case, patients treated on the first or second day of the disease, in most instances, showed a prompt cessation of all symptoms within a few days. When treatment was delayed beyond this period, there was a sharp rise in the incidence of secondary complications and their severity.

Number of Cases	132	97	22
Antitoxin given on	1st and 2nd days	3rd and 4th days	After 4th day
Adenitis	3.7%	7.2%	4.5%
Otitis media	6.1%	8.2%	18.1%
Mastoiditis	. .	1.03%	13.6%
Nephritis	. .	1.03%	4.5%
Sinusitis	. .	2.0%	. .

For maximum clinical response, institute antitoxin therapy early and in adequate dosage.

The coming of the Globulin-Modified antitoxin largely relieves the physician from the old fears of reactions and clears the way for the use of the ideal therapy, even in the mildest cases, reducing the incidence of secondary complications.

The Wider Field of Application of BALANCED ALKALINE MEDICATION

HYPERCHLORHYDRIA, hyperacidity, nervous dyspepsia and ulcers of the stomach and duodenum have always been considered as conditions for which alkali medication is indicated, but there are also pathological manifestations far removed from these conditions which have been found to respond to proper alkaline medication.

Clinical experience has shown that the alkalies chosen in 'BiSoDoL,' viz. sodium bicarbonate and magnesium carbonate, are therapeutically an ideal combination. The sodium bicarbonate offers the system a readily available alkali and the insoluble basic carbonate provides pronounced alkalinizing powers against acidity as it arises. The mixture presents a combination of unusual buffering agents and avoids therefore the possible danger of alkalosis, which is associated with the administration of a single alkali.

While the formula of 'BiSoDoL' was originally evolved for the correction of acid conditions of the stomach, so suitable has it been found in balanced alkaline medication, that it is now largely prescribed in this wider field.

BRAN

the safest method of remedying the deficiencies of

BULK

in modern diet

7½D Per Packet

CHRONIC CONSTIPATION YIELDS TO BRAN REMEDY

The problem of balancing up the lack of bulk in diet and so ensuring normal bowel action is one which is solved by the addition of Kellogg's ALL-BRAN to the diet. ALL-BRAN is a natural laxative food and is rich in Vitamin B and iron.

ALL-BRAN cleanses like a *water-softened sponge.* Within the body the soft "bulk" of ALL-BRAN gently exercises intestinal muscles, and *sponges out* the system ensuring natural and regular elimination. Some patients eat Kellogg's ALL-BRAN, served from the packet, with cream or milk. Others prefer it cooked into biscuits, cakes or omelettes.

Except in cases of hyper-sensitive digestive tracts, Kellogg's ALL-BRAN can be safely and confidently prescribed. Full-sized sample packet free on request.

Haemolytic streptococcal infections

STREPTOCIDE

(*p-aminobenzenesulphonamide Evans*)

For oral administration

The therapeutic indications include:

Acute puerperal sepsis, erysipelas, tonsillitis and the sequelae of these conditions and as a prophylactic measure

Streptocide minimises the risk of septicaemia in Caesarean section and abortion and prevents such complications as otitis media, mastoiditis, arthritis and endocarditis (when attributable to haemolytic streptococci) in scarlet fever, tonsillitis, rheumatic fever and measles.

STREPTOCIDE is issued in tablets as follows:—

	0.5 grm. (7½ grains approx.)	0.25 grm. (3¾ grains approx.)
In bottles of 25 Tablets	2/9	2/-
„ 100 „	9/-	6/6
„ 250 „	21/-	15/-

Please indicate the strength desired when prescribing.

Fiat tablet - - - -	0.35 ,,

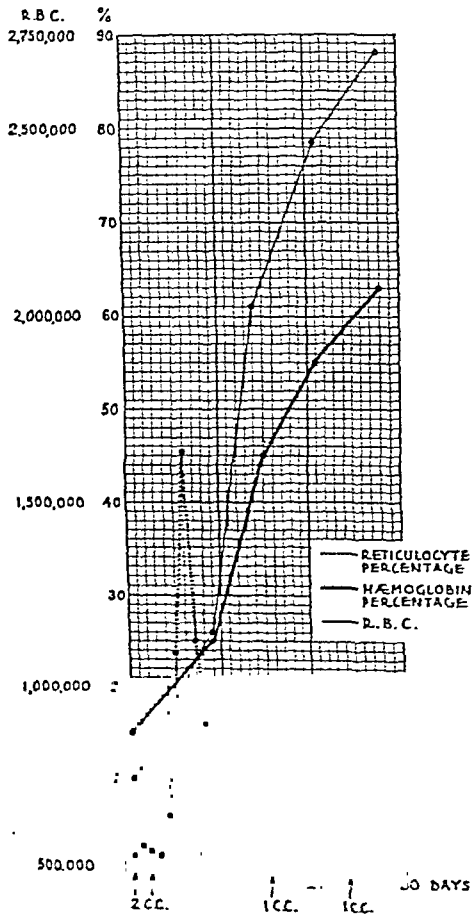
Initial Daily Dose
Two Tablets

Laxatives, it is well known nowadays, must have two essential characteristics.

1. They must be biological, i.e., they must accord with and imitate in their action the natural physiological processes of the intestine.
2. They must be capable of educating the intestine, so that the habit of a laxative is not formed and the intestine can function unaided when bowel adjustment is attained.

Taxol has both these advantages.

Taxol has not the violent irritant action of many laxatives and purgatives, but stimulates the intestine by processes which resemble those of nature. The intestinal gland which is an important part of its composition acts on the intestine by reinforcing the deficient function which has culminated in constipation. This stimulating action is gentle, and does not force the weakened intestine to efforts beyond its power, which would culminate in aggravation of the constipation.



Taxol is not habit-forming. It re-educates the intestine to resumption of normal function unaided, thanks to the biological nature of its action. It contains no irritant drug of violent and artificial action to which the intestine can become accustomed. On the contrary, many stubborn cases of constipation, after a course of TAXOL, revert to normal and regular peristalsis.

ANAHÆMIN B.D.H.

In the treatment of pernicious anæmia

Physicians who have adopted anahæmin treatment as a routine in pernicious anæmia testify to the uniformly beneficial effects which invariably result.

The graph reproduced herewith illustrates the response to three injections of anahæmin in a case recently reported (Brit. Med. Journ, May 22, 1937, p.1090).

In commenting upon the result obtained the physicians concerned stated '...until recently we should undoubtedly have transfused this patient before treating her with liver extract, but similar experience with two other severe cases treated with anahæmin has given us sufficient confidence to wait for the expected reticulocyte crisis about the fifth day.'

Cystopurin

The ideal urinary antiseptic for oral administration!

1 Produces no gastric irritation or toxic symptoms.

2 Is readily absorbed from the gut and excreted in the urine.

3 Causes no renal irritation.

4 Renders the urine bactericidal in low concentrations.

5 Acts from the renal pelvis downwards.

6 Is active in either acid or alkaline urine.

7 Perfectly safe for use in febrile conditions.

8 Acts on all causative organisms of urinary infections.

PROSTATITIS

From information received :—

"The Cystopurin—I had good results in one case. A man of about 64 with a small fibrous prostate, suffering from frequency and retention. Three tablets daily cleared up his symptoms in six weeks except for a little nocturnal frequency, but all pain, straining and scalding had gone. He had been on various mixtures before for three months with no result."

"I am very pleased to say that Cystopurin is certainly having satisfactory results with a case of cystitis due to cancer of the bladder.* I find it also satisfactory in gonorrhoea and prostatitis."

"In a case of chronic prostatitis and cystitis in a man aged 61, Cystopurin greatly improved the condition of urine and frequency of micturition. Patient has had lately very good nights. Bacterial examination, no pus in urine."

"I have pleasure in reporting to you on my experience of Cystopurin. I have in the past used it in intractable cases of cystitis or prostatitis and have had very good results."

"Male aged 56. This man had delayed coming forward for treatment for about a month and was in a very serious condition. He had an acute urethritis with prostatitis and orchitis, the testicle being about the size of an orange. His temperature was 103.4° F. Pain was extreme and he was afraid to micturate. He was put on treatment at once but with very poor results. I administered Cystopurin tablets in the dosage of two t.i.d. At the end of the third day an improvement was noticed, the temperature having fallen to 100° F. The dose was then increased to three t.i.d. At the end of a fortnight the prostate was considerably reduced in size and much less tender, and the testicle was nearly normal in size and painless. Progress was thereafter uninterrupted, the first negative smear being returned much sooner than was anticipated. The dose of three tablets t.i.d. was reduced to one t.i.d. when the temperature became normal on the seventh day.

"I am sure that this man's illness would have been of much longer duration but for Cystopurin."

Supplied in bulk and in tubes of 20 tablets for dispensing purposes.

Samples and literature available on request to

COLLOSOL BRAND PHOSPHO-MANDELATE

(for Urinary Sterilisation)

IN A NEW PACKING

This new and simple treatment for urinary infections, embracing cystitis and allied disorders, completely supersedes the difficult and nauseating ketogenic diet and consists in first rendering the urine acid by the administration of ammonium phosphate and then giving mandelic acid; the fluid intake of the patient being restricted to maintain as high a concentration of the acid in the urine as possible.

The cost of the 6-days treatment is 5/-.

Suitable test papers with comparison tints of different pH levels are also supplied.

Full particulars upon request.

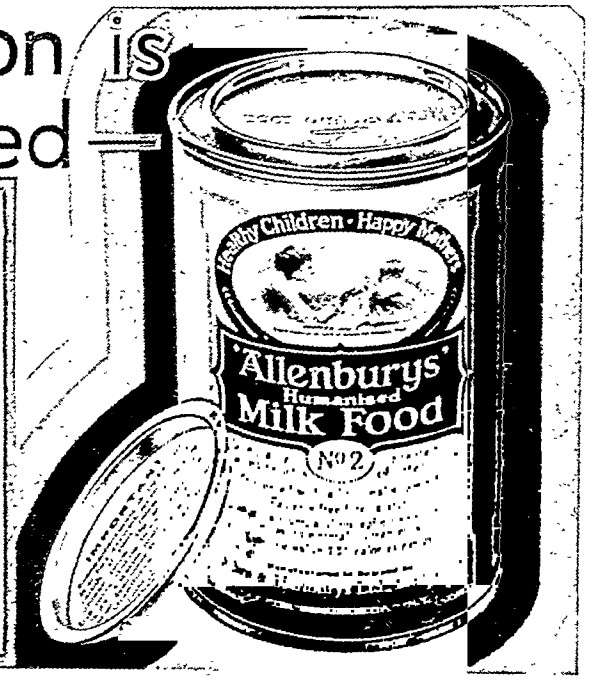
THE THERAPEUTIC VALUE OF THE BANANA

III. Coeliac Disease

This nutritional disturbance of early childhood has been found by *Haas* to give way very satisfactorily under treatment with bananas. The carbohydrates of the banana are tolerated perfectly, and combined with sour milk give a diet of high calorific value. The maximum number of bananas used in any one case was sixteen daily for a child of twenty-six months.



The *Haas* treatment is now being extensively used in European children's hospitals with excellent results. The method of administration is usually to rub fully ripe bananas through a sieve, and beat to a cream pulp with milk or other suitable liquid.

N.B. In the fully ripe banana the starch content is reduced to about 3 per cent, having been changed into soluble sugars. A banana is ripe when all green has disappeared from the skin and brown spots have formed upon the yellow surface.

Vitamin Concentrate or Natural Food?

The normal daily dosage, (i.e. ½-ounce), of Bemax, the natural vitamin tonic food, provides 200 International units of Vitamin B_1, which is from four to ten times as much as the daily dosage of certain Vitamin B_1 "concentrates" advertised to the medical profession.

If a higher intake is required, it is possible to supply as much as 600 to 800 units of Vitamin B_1 daily by the administration of three to four tablespoonfuls of Bemax, and this in an entirely natural form at only a fraction of the cost of such concentrates.

The Vitamin B_1 potency of Bemax is assured by biological assay of every day's output.

BEMAX

A unique natural source of accessory nutritional factors

Vitamin B_1 — 400 International Units per ounce.
Vitamin B_2 — Flavin present.
Vitamin B_6 — (Anti-dermatitis) One of the richest sources.

Vitamin A—280 International Units (as Carotene)
Vitamin E—the richest natural source;
Phosphorus—330 mg. per ounce;
Magnesium—99 mg. per ounce;
Iron—3 mg. per ounce, and Copper =0.45 mg. per ounce.

INFLUENZA: FOUR YEARS' PROGRESS*

BY

C. H. ANDREWES, M.D., F.R.C.P.

(From the National Institute for Medical Research, Hampstead, London, N.W.3)

Influenza is a disease with which we are all familiar, either as doctors or as patients. Yet it is a disease concerning which exact knowledge has been lacking, whether from the clinical, the epidemiological, or the pathological point of view. The reason is this: the term "influenza" has been used to designate a scrap-heap of upper respiratory tract infections, and one can never be sure in reading any two descriptions in the literature that the writers are referring to the same disease.

In the absence of any exact method of clinical or pathological diagnosis the only attempts to define the disease have been on an epidemiological basis; and this is not very satisfactory for ordinary mortals, whatever it may be to epidemiologists. I propose to-day to try to convince you that it has recently become possible to separate off from the influenza scrap-heap a definite disease, one, moreover, which is probably responsible for the more important outbreaks labelled "influenza." The basis of separation is in the first place aetiological: one can recover from garglings in the early stages a virus which will infect ferrets and mice. My colleague Dr. Stuart-Harris will describe later in the discussion attempts made to recognize the disease from a clinical standpoint. The results I shall now describe are based chiefly on experimental work, some of it unpublished, carried out jointly by my colleagues Dr. Wilson Smith, Sir Patrick Laidlaw, and Dr. Stuart-Harris, and myself.

The Disease in Ferrets

To recover virus from a patient unfiltered garglings are dropped from a pipette on to a ferret's nose. When virus is present in the inoculated material the ferret shows fever and nasal symptoms after about forty-eight hours. It goes off its food, lies about apathetically, and develops nasal discharge, sneezing, and, later, pronounced nasal obstruction. The temperature chart often shows two spikes forty-eight hours apart. Influenza in the ferret is infectious by contact, and to guard against cross-infections we isolate each animal in a separate cubicle.

When we appear to have infected a ferret with material from a patient we usually kill the animal at the height of its disease on the third or fourth day. We then find that the mucous membrane over its turbinate bones is engorged and that the nasal cavities are full of muco-pus. We remove the turbinates and grind them up with sand; an emulsion is obtained which can be filtered and studied in other ways to prove that it really is influenza virus which has produced the symptoms.

As a rule influenza virus will only infect ferrets when introduced directly into the respiratory tract. If passages are made without the use of an anaesthetic no pneumonia will be produced, but by serial passages in anaesthetized ferrets one can obtain a modified virus which will produce extensive, often fatal, lung lesions (Shope, 1934). These lung lesions are commonly bacteriologically sterile. The affected lungs are firm and purplish red, and much moisture can be squeezed from their cut surfaces. Histologically bronchitis and bronchiolitis are prominent features. There is patchy atelectasis and exudation of fluid in the alveoli with peribronchial infiltration of cells, chiefly mononuclears. But polymorphonuclear infiltration is not a feature, nor are the alveoli packed with cells. It is of much interest to know that a biologically modified strain of virus can be obtained having such a predilection for the lungs; also that lung lesions of this type can be produced by the virus *alone*, without, so far as we can see, any assistance from secondarily invading bacteria.

Adaptation of the Virus to Mice

Virus adapted to ferret lungs will infect mice without any difficulty, but we have had varying success in our attempts to adapt recently isolated human influenza strains to mice. All but one of a number of strains isolated in 1935 infected mice readily after only two or three passages in ferrets (Andrewes, Laidlaw, and Smith, 1935). This year we have found such adaptation more difficult: several strains of virus have refused to infect mice even after a number of ferret passages. Hoyle and Fairbrother (1937) appear to have had the same experience. Lately we have discovered that the failure of some strains to infect mice is only apparent; there is actually merely a failure to produce macroscopic lesions. If inoculated mice are killed on the third day after infection, and more mice are infected with an emulsion of their lungs, and so on, one will ultimately succeed in obtaining visible lesions in the lungs of the mice perhaps after three, perhaps only after six, passages. Quite recently Francis and Magill (1937a), using such a passage-by-faith technique, have reported success in obtaining direct man-to-mouse isolation of influenza virus without the use of ferrets at all. The importance of this to workers in laboratories where ferrets are unobtainable is obvious.

The Disease in Mice

In mice the virus produces lesions of the lungs only; the nasal passages are not affected. Perhaps in relation to this fact influenza in mice is entirely non-contagious; *normal* mice kept in the same cage as infected ones neither contract the disease nor become immune. This makes work with mice much easier, but, on the other hand, we lose the opportunity of what would be a really exciting study in experimental epidemiology. When first adapted to mice influenza is a relatively non-fatal disease; but after

* Read in opening a discussion in the Section of Pathology, Bacteriology, and Immunology at the Annual Meeting of the British Medical Association, Belfast, 1937.

many passages it becomes more lethal, and infections can be produced with one ten-millionth of a cubic centimetre of filtrate. Filtrates are readily neutralized by immune sera, and a neutralization test that has yielded much interesting knowledge is thus made available.

Evidence that the Virus is the Cause of Influenza in Man

I will now summarize the evidence which convinces us that the virus we are studying is the primary cause of epidemics of influenza in man.

1. First, we have recovered the virus from garglings of fifty-three patients with the symptoms of influenza obtained at times of rather widespread prevalence of the disease. During the recent epidemic virus was isolated from thirty-one out of forty-one uncomplicated cases tested. Virus has only been obtained during the first few days of infection and not during convalescence. We have failed to recover the virus from normal people, and we have usually failed also with garglings from sporadic cases or patients in localized outbreaks diagnosed as influenza but occurring in the absence of a widespread epidemic.

2. The virus has been recovered as described above from influenza garglings taken during outbreaks not only in London (Smith, Andrewes, and Laidlaw, 1933), but from all over the world—in the West Indies, United States, and Alaska (Francis, 1934), in Australia (Burnet, 1935), in Russia (Smorodintseff, *et al.*, 1936a), in Holland, and, during the recent outbreak, in Manchester, France, Germany, Hungary, and again in the United States.

3. The serum of patients taken during the acute stages of infection is found to have little or no power to neutralize the influenza virus. But as early as the eighth day of the disease it will have acquired very definite neutralizing powers. No such neutralizing powers appear in the sera of patients suffering from respiratory diseases other than influenza. We now have some evidence that sera from the population at large, including people who have not recently suffered from influenza, contain better neutralizing antibodies just after an epidemic than just before one.

4. In 1933 we made two attempts to infect volunteers with virus which had been passed serially through ferrets; these were unsuccessful, but at the time we failed to obtain any volunteers who had not good antibodies in their sera, and such antibodies may have protected the two victims of this experiment. Last year an accident completed our chain of evidence for us. A ferret infected with a virus which had been passed in series through 196 ferrets sneezed upon Dr. Stuart-Harris and produced in him a typical attack of the disease. There was no influenza prevalent at the time, and the virus recovered was distinguishable by its biological effects from ordinary strains of human origin. There is therefore almost no room for doubt that Stuart-Harris's infection actually came from the ferret (Smith and Stuart-Harris, 1936). Smorodintseff and his co-workers (1936a) have recently recorded their success in infecting five human volunteers with the virus.

5. The irregularity with which Pfeiffer's bacillus has been recovered from influenza epidemics is notorious and cannot be explained away by blaming differences in technique. Smorodintseff *et al.* (1936) have lately carried out extensive attempts to infect volunteers with cultures of Pfeiffer's bacilli, but produced nothing comparable with influenza. Experimental "swine 'flu" has been demonstrated by Shope (1931) to be due to the combined action of a virus and a bacillus related to Pfeiffer's bacillus. On the other hand, experimental influenza in ferrets and mice is a pure virus disease in which bacteria ordinarily play no part. The evidence at present suggests that ordinary influenza in man resembles the disease in ferrets and mice in being purely a virus infection; further, it seems likely by analogy that the virus alone may cause pulmonary complications; but it is all too familiar to us that streptococci, pneumococci, staphylococci, and Pfeiffer's bacilli may on occasion play a very serious part as secondary invaders of the lung.

Immunological Aspects

Naturally we are all interested in possible practical applications of recent work on influenza, particularly in the possibility of prophylactic vaccination. In order to make the matter clearer I must first relate something about immunity in ferrets and mice.

IMMUNITY IN FERRETS

Ferrets which have recovered from an attack of influenza develop potent neutralizing antibodies in their sera and are completely resistant to reinfection for about three months. But after six months their immunity has definitely waned; antibodies, though still recognizable in their sera, are less than before, and the animals will develop some fever and nasal symptoms when a heavy dose of virus is given intranasally.

As already mentioned, influenza virus given subcutaneously or by routes other than into the respiratory tract does not infect—or only very exceptionally. It will, however, produce some immunity, especially when several doses are given. The immunity produced by vaccination is shown by: (i) the production of antibodies; (ii) the milder nature of the fever and symptoms; (iii) complete protection against the development of lung lesions; (iv) protection against the less severe test of exposure to contact with an infected ferret; (v) restoration of waned immunity to the complete state. By this is meant that ferrets whose immunity has fallen off six months after an infection are rendered once more completely immune by one dose of subcutaneous vaccine (Smith, Andrewes, and Laidlaw, 1935).

It would be more satisfactory if normal ferrets could be completely immunized by vaccination, but the results as they stand are not discouraging. It must be remembered: first, that human beings in an epidemic are exposed only to contact infection, against which vaccination does protect ferrets, not to massive intranasal instillations of virus; secondly, that almost all adult human beings have been exposed to influenza in the past and thus have some basic immunity which merely requires reinforcement. They are thus comparable rather to the ferrets with waned immunity than to fresh untreated ones.

IMMUNITY IN MICE

In mice influenza is a disease of the lungs; and just as vaccination is very effective in protecting ferrets against lung lesions, so it is in mice. Two subcutaneous or intraperitoneal injections give a substantial immunity; in many experiments all the mice of a vaccinated group have survived a dose of virus which has killed all, or almost all, controls. Further, when the vaccinated mice have been killed at the close of the experiment the lungs of most have appeared normal. After two doses of vaccine the immunity of mice appears to last for ten but not for sixteen weeks; this is as long as the immunity of mice which have actually recovered from an infection. Protection experiments in mice have lent themselves to the quantitative study of a number of problems, particularly those designed to find a suitable vaccine for use in man.

A most important result of such studies is the finding that virus inactivated by 1 in 5,000 formaldehyde is almost

if not quite as effective an antigen as is living virus. It is still the fashion, particularly in America, to make the statement that a "killed" virus cannot immunize. Influenza virus inactivated by formaldehyde appears by all the tests we can apply to be as dead as a doornail, and I feel that it is rather up to anyone who maintains that it is still alive to produce some supporting evidence.

It is satisfactory to be able to use a safely inactivated virus; it would be better still if we could use one freed from unwanted proteins. Virus filtrates have accordingly been washed on a collodion membrane with pores of such a size that the virus is all held back while the mouse proteins are washed through the membrane. Thus is obtained a water-clear fluid as effective in immunizing mice as the untreated filtrate. Most unfortunately it is found that while formolized virus is almost as effective an antigen as living virus, and purified virus is as effective as unpurified, yet virus which has been both formolized and purified fails to act as a good vaccine—we do not know why (Andrewes and Smith, 1937).

This is particularly unfortunate, since it appears that the presence of foreign protein interferes with the antigenic response to a virus. Thus we found that vaccine made from infected mouse tissues was very effective for immunizing mice, while vaccine made from infected ferret tissues was not. Shope (1936) has observed the same thing. Lately we have discovered that if mouse vaccine is mixed with an extract of normal ferret tissues the immunizing effect of the vaccine for mice is badly interfered with.

Vaccination of Man

Though we have not yet succeeded in eliminating the mouse protein from the vaccine available without spoiling it, we have made preliminary attempts at vaccinating human beings. Francis and Magill (1937) have made similar attempts, using living virus grown, as many viruses can be grown, on tissue cultures of chick embryo. They have succeeded with such a vaccine in inducing a rise in antibodies in the vaccinated subjects. Stokes *et al.* (1937) have also used a living vaccine made from mouse tissues, and claim that there was a lower incidence of influenza among the vaccinated members of the community they studied than in the control group; there is, however, no certainty that the respiratory disease which afflicted that community really was epidemic influenza. We have chosen to err on the side of caution by using only formalin-inactivated virus, and we too have followed the neutralizing antibodies in the people we have vaccinated. One dose of 2 c.cm. of vaccine subcutaneously has produced only a trifling local tenderness and has engendered a very satisfactory rise in antibodies. Among thirty volunteers, all soldiers at Woolwich, we obtained an average increase in antibodies of twenty-five-fold when we compared bleedings taken a fortnight after vaccination with those obtained beforehand. A few results of ours confirm those of Francis and Magill that not much rise occurs until after a week from the time of injection. A satisfactory feature was that one dose of vaccine produced as good an antibody rise as did two spaced a fortnight apart.

Encouraged by these results we began last December to make enough vaccine to inoculate larger numbers of people and to test whether an actual resistance to natural infection would be produced. It was arranged through the kind co-operation of the Army authorities to vaccinate five groups, each of about 100 men, in different units and to designate similar numbers as comparable controls. But scarcely had we begun when the epidemic burst upon us. We did not expect from the serological results that any active immunity would be produced until at least a week after injection, and it happened that in most of the vaccinated and control groups influenza appeared within a day or two of the vaccination. In two groups no influenza occurred amongst either the vaccinated or the unvaccinated controls. We thus have no certain evidence as to the efficacy of the vaccine. There is, however, suggestive evidence that the vaccine is not as good as we should like it to be. Four persons, vaccinated at least a fortnight beforehand, nevertheless developed clinical influenza, and from them we obtained the virus; so we at least know that the method is not 100 per cent. perfect.

And now there has arisen a new complicating factor. We no longer feel sure that all strains of human influenza virus are serologically identical. Magill and Francis (1936) reported lately that two strains of human influenza virus isolated by them in 1934 could be sharply distinguished from each other serologically by means of anti-sera made in rabbits by a particular method. We have been repeating this work, and have reason to suspect that the two strains which they have separated, both of them carried for many generations in tissue culture, have become antigenically changed in the course of this propagation. This might lead us to doubt the importance of the differences found. On the other hand, we have observed that some strains of virus isolated in England in 1937 are not identical with the W.S. strain with which we have worked since 1933 and which we used to prepare our vaccines. The difference is revealed by titrations of ferret sera as well as of rabbit sera, and also in cross-immunity experiments. There is a considerable antigenic overlap, and the strains are more closely related to each other than to the swine-influenza virus; but there are distinct differences. The importance of differences between strains to prophylaxis and to epidemiological studies one can at present only guess at. The tangle is not going to be an easy one to unravel.

Conclusion

I will conclude by re-emphasizing three main points:

First, epidemic influenza in man is caused by a virus which is transmissible to ferrets and mice.

Secondly, progress in our knowledge of influenza may largely depend on our recognition that this specific disease has hitherto been mixed up with other respiratory infections.

Thirdly, there are grounds for hope that an effective prophylactic against influenza may be found, though there are still many obstacles to overcome.

EPIDEMIC INFLUENZA

A CLINICAL POINT OF VIEW*

BY

C. H. STUART-HARRIS, M.D., M.R.C.P.

(From the National Institute for Medical Research, Hampstead, London, N.W.3)

Although the filterable virus of epidemic influenza was first isolated in 1933, no work has been carried out until recently which has combined a clinical and a pathological study of the virus disease. During 1936 we investigated clinically and attempted to isolate virus from four localized epidemics which had been diagnosed as influenza. We did not recover virus, and we obtained serological evidence that the virus was not concerned. Then in December, 1936, the widespread influenza epidemic afforded us an opportunity of correlating the clinical events in man with the isolation of the virus from individual patients. Most of the clinical work in these combined investigations was for several reasons carried out upon patients in the Services. Chief among these were the facts that the men were all healthy before the illness, so that the picture of the disease was clean; and, secondly, that the patients were admitted to hospital early in the course of the disease, which enabled the whole illness to be studied and facilitated the recovery of the virus.

The principal question throughout the work has been whether influenza virus infection in man constitutes a clinical entity or not. Experience in a further epidemic and in the civil population will have to be gained before our tentative conclusion that it does constitute an entity can be proved. The evidence for believing that we were dealing with an entity during the recent epidemic was threefold. First, the disease presented a remarkably uniform clinical picture, case after case exhibiting similar features. It is true that the severity of the disease varied somewhat in the different areas, but the general picture was everywhere the same. Secondly, this characteristic clinical picture was correlated with the recovery of virus from the throat in a high proportion of cases. We were not able to test every patient owing to the number of ferrets required, but representative individuals from groups of similar clinical type were chosen and virus was isolated from twelve out of fifteen patients with straightforward influenza who were tested and whom I saw myself. Thirdly, the clinical picture we attempted to delineate during the 1936–7 epidemic differed from that seen in previous epidemics which we had studied and from which virus was not obtained.

Variations in Clinical Type and Experimental Analogies

During the influenza epidemic certain analogies became evident between influenza virus infection in man and the experimental disease in ferrets and mice—particularly between man and the ferret. Influenza virus can produce in the ferret either a short fever with lassitude, nasal symptoms, and nasal lesions, or an illness accompanied by the development of lung lesions varying in extent from small patches of bronchiolitis and atelectasis to fatal pneumonic consolidation. Similarly, although the more usual illness in man that was of virus aetiology was a three-day or four-day fever with constitutional symptoms and signs of upper respiratory tract infection, other cases from which virus was obtained had signs of chest disease. The commonest type of chest abnormality was a basal condition with rales and suppressed breath sounds, which I believe to be due to a bronchiolitis with patchy atelectasis or scattered areas of consolidation. Virus was isolated from each of five patients tested who had signs of this condition. Frank pneumonic cases, however, did not usually yield virus from garglings and sputum by the time that lung signs were definite, but bacteria such as pneumococci were then recovered; however, one case of pneumonia yielded virus from garglings and sputum on the fifth day of the disease, when consolidation of lobar distribution was present, and virus was also recovered from the lungs in three rapidly fatal cases of pneumonia.

An interesting example of the similarity of the infective process in man and the ferret was seen in connexion with the pyrexia. Several different types of fever were observed in man, including a single peak, a remittent fever, and a fever with two peaks. This latter type, which was seen in 25 per cent. of patients, was of special interest, because it resembled the diphasic fever seen so commonly in ferrets infected with influenza virus.

In addition to the typical cases of influenza a number of mild infections and afebrile patients with symptoms were seen in some of the epidemic areas. Two afebrile patients were tested for virus, but this was not recovered, and although it is possible that such cases represented abortive infections by the virus, such as have occurred very occasionally in the ferret experimentally, we have no proof that the human infections were so caused. Suggestive serological evidence was obtained that subclinical infections by the virus can occur in man; and if this is so, then afebrile patients with symptoms would logically form the next grade of severity to such silent infections.

Finally, some patients presented the ordinary picture of the epidemic disease but suffered from repeated vomiting at the onset of illness. One such case was tested, and virus was recovered from the throat, but another patient who suffered from diarrhoea as well as vomiting and had no respiratory symptoms did not yield virus. No other cases with intestinal symptoms were seen throughout the epidemic, and so, although a form of infection with gastric symptoms at the onset can be due to the virus, there is no proof of the existence of a separate and distinct gastro-intestinal form of the virus infection.

Differentiation of Epidemic Influenza and "Febrile Catarrhs"

With regard to the question of differentiating the virus disease from other conditions resembling epidemic influenza, the form of the epidemic may help. At Chatham where cases from the naval barracks were studied, an epidemic occurred in November, 1936, of tonsillitis and of a pharyngo-laryngo-tracheitis disease. Influenza virus was not recovered at this time, but in January, 1937, a sharp epidemic occurred and virus was now found. The explosive onset of the influenza epidemic contrasted with the slow rise of the previous epidemic from the endemic respiratory infections. Again, the influenza epidemic was soon over in each area and rarely lasted longer than a fortnight; secondary waves were seen, particularly at Chatham, but in each case these were due to the spread of the epidemic among new entries to the barracks, either those returning from leave or visitors to the port. Finally the influenza epidemic consisted of cases of similar clinical type though varying in severity, while the previous Chatham epidemic included two groups of cases, one with frank tonsillitis and the other with pharyngo-laryngo-

* Read in opening a discussion in the Section of Pathology, Bacteriology, and Immunology at the Annual Meeting of the British Medical Association, Belfast, 1937.

tracheitis. For these latter cases, which yielded no evidence of influenza virus infection, we propose to use the term "febrile catarrhs." It must be emphasized that the name refers to a group of conditions forming the scrap-heap of epidemic respiratory infections resembling influenza but of unknown aetiology, and not to a specific condition.

On clinical grounds the first symptoms of illness which are complained of show a sharp contrast between epidemic influenza and febrile catarrh. Table I

TABLE I.—*Symptoms at Onset*

		Epidemic Influenza	Febrile Catarrhs
Premonitory symptoms		13 per cent.	28 per cent.
Sudden onset		75 "	42 "
Symptoms during the first 24 hours of illness	Headache	54 "	17 "
	Shivering	39 "	10 "
	Muscular pains	21 "	7 "
	Cough	20 "	35 "
	Malaise	18 "	3 "
	Coryza	15 "	21 "
	Insomnia	14 "	1 "
	Sore throat	11 "	42 "
	Dizziness	11 "	14 "
	Vomiting	6 "	0 "
	Fainting	2 "	0 "
	Abdominal pains	1 "	0 "
	Sweating	1 "	0 "

shows an analysis of the symptoms at the onset in eighty-four cases of straightforward influenza contrasted with those in twenty-eight cases of febrile catarrh.

TABLE II.—*Symptoms During the Course of the Fever*

	Epidemic Influenza	Febrile Catarrhs
Malaise	91 per cent.	82 per cent.
Headache	87 "	64 "
Anorexia	77 "	70 "
Shivering	74 "	70 "
Coryza or nasal obstruction	73 "	70 "
Cough	71 "	86 "
Dizziness	62 "	64 "
Muscular pains	51 "	53 "
Sore throat	43 "	80 "
Ocular symptoms	33 "	21 "
Insomnia	32 "	43 "
Sweating	31 "	50 "
Expectoration	30 "	50 "
Pains in chest	24 "	40 "
Epistaxis	21 "	21 "
Constipation	21 "	23 "
Nausea	21 "	3 "
Vomiting	11 "	23 "
Dyspnoea	11 "	0 "
Abdominal pain	8 "	23 "
Hoarseness of voice	6 "	43 "
Fainting	4 "	0 "
Faintness	2 "	3 "
Diarrhoea	0 "	3 "

Premonitory symptoms such as coryza, sore throat, or cough are uncommon in influenza, which starts abruptly in the midst of good health. In febrile catarrh, however, the disease begins frequently with a cold, and fever follows in some days' time. Moreover, the first symptoms in influenza are of the general or constitutional type and not of a respiratory nature. Considering the symptoms throughout the fever (Table II) the contrast is less striking. Again, however, general symptoms dominate the illness in influenza, and local respiratory ones predominate in febrile catarrh. Certain symptoms deserve special mention. Cough was short and dry in influenza, but paroxysmal, tearing, and barking in febrile catarrh. In association with the cough, substernal soreness of the chest was more striking in febrile catarrh, which is often a tracheitis. Sore throat is not a feature of influenza, but is constant in febrile catarrh. Laryngitis is rarely severe in influenza, but a very hoarse voice is common in febrile catarrh. Certain other symptoms, however, such as muscular pains and epistaxis, show no difference in frequency in the two diseases.

The differences are summarized in Table III, and there is no doubt that the two conditions show a contrast when the cases are considered in groups. The difficulty arises when individual patients are seen. Then the general

TABLE III.—*Differential Diagnosis of Epidemic Influenza and Febrile Catarrhs*

	Epidemic Influenza	Febrile Catarrhs
Onset	Sudden	Insidious
Symptoms	Constitutional symptoms preponderate	Respiratory symptoms preponderate
Cough	Short and dry	Paroxysmal, irritating, painful, often productive
Voice	Husky	Hoarse
Throat	Posterior pharyngitis; no exudate	Tonsillitis as well as pharyngitis; exudate common
Fever	Sometimes diphasic	Rarely diphasic
Complications	*Bronchiolitis and pneumonia*	*Bronchitis or bronchopneumonia*
Epidemic	Short, with rapid "peaking"	Prolonged and "grumbling"
Contacts	Clinical picture uniform, although graded in severity	Clinical picture variable, with frank tonsillitis in contacts
Leucocyte count	Not diagnostic	Not diagnostic
Virus	Influenza virus recoverable from pharynx	Influenza virus not concerned

appearance may help, for this is very characteristic in typical influenza, being heavy with drooping eyelids half covering suffused and watering eyes, a dusky malar flush, an obstructed but not running nose, and a furred tongue. The pharyngitis of influenza involves the posterior wall and is dry in contrast with the moist tonsillar and pharyngeal inflammation of febrile catarrh, which often exhibits exudate. Nothing comparable with the bronchiolitis and influenzal pneumonia cases seen recently was encountered in the previous epidemics, although a basal bronchitis or a bronchopneumonia occurs as a complication of febrile catarrh. The blood count was not of help in diagnosis, no definite abnormality being found in the leucocytes in either disease, and the absence of leucopenia, post-influenzal debility, and depression from the patients in the Services during the recent epidemic was surprising in view of the general belief in these phenomena as criteria of influenza.

In conclusion, I cannot say that it is possible to diagnose epidemic influenza with precision, but I hope I have convinced you of the existence of a clinical entity in that epidemic disease which is associated with the influenza virus.

We are extremely indebted to the Admiralty, the War Office, and the Air Ministry for their permission to work in Service hospitals, and would also like to thank all the officers concerned for their kind co-operation.

STRUCTURE OF THE PERSONALITY IN PSYCHOTHERAPY*

BY

PROFESSOR ERNST KRETSCHMER

Director, Psychiatric and Neurological Clinic, Marburg University

Medical treatment by psychological methods is governed by certain guiding conceptions. In the older psychotherapy the leading principle is that of suggestion; in the more recent that of psycho-analysis. In neither is the study of the finer structure of the personality the aim. Suggestion can very well be practised as mass or group suggestion; in fact, frequently those suggestions are strongest and most effective which ignore the single individuality and bring it down to a common level. In the psychoanalytical schools it is the problem of experiences, their elaboration, transformation, and after-effects, which is in the foreground; the other half, the inner structure of the personality which is influenced thereby, receives little attention. It is not at this moment my purpose to state my attitude to all these various methods of psychotherapy, but rather to tackle the problem for once from the opposite side, to show it in the light of the personality and its inner biology.

The Meaning of "Structure of the Personality"

When we speak of the "structure of the personality" we have in mind, as the term implies, something more or less rigidly built up, a structure or a system of structures, a series of a certain number of "qualities" which can be defined in words and which manifest themselves in such and such a manner. This structure would have gradually taken shape and developed through the bilateral operation of the constitutional make-up and the outside world, particularly in childhood and youth. In adults it could figure as a fairly definite constant calculable factor, especially in those cases in which, in the course of psychotherapy, one has to study its typical responses to the outside world. This line of thought links up with the concept which would equate an individual's inherited equipment with that which is constant or fixed in his personality, a point I will refer to later.

The question, What is inherited in the personality? is indeed of fundamental importance not only for eugenics but also for psychotherapy, because, conversely, it is on this that the question depends: What has accrued to the personality from the outside, and can hence be modified by outside influence? But first of all an important question must be outlined more precisely. Generally one starts out from the tacit premise or equation, "psychogenic = responsive to psychotherapy"; in other words, everything that has originated by way of the psyche can also be removed by way of the psyche, and, conversely, all endogenously derived pictures are outside the scope of psychotherapy. Although these propositions, as applying both to the healthy and to the diseased personality, approximate to the truth they call for critical inspection.

The Negative Thesis in Psychotherapy

Already the negative thesis, "endogenous = non-responsive to psychotherapy," has proved to be not altogether valid. There are, however, optimists who state that schizophrenia can be cured by psychotherapy; I have never yet seen evidence of this in severe progressive cases. It would imply that the schizophrenic process is reversible down to its roots by psychotherapy. But let us bear well in mind the difference between "reversible" and "formable." If we cannot bring about an involution of the endogenous elements of the schizophrenic process by psychic means we can nevertheless maintain that the form which it takes can be influenced by psychotherapy at every stage. This is especially the case when the endogenous process no longer shows acute progression. Today it is no longer seriously contested that we have been regarding the schizophrenic symptoms far too much as a finished product, as it were, of the endogenous process. The more active treatment of patients, as it is now legitimately practised in mental hospitals, has shown that even the severe final stages can be modified; this means that complicated symptoms and powerful dynamic manifestations of the psychosis can be made to disappear partially through psychic influence, and that in their place responses can be produced which are nearer to those of healthy subjects. The pictures are therefore reduced to their innermost and truly endogenous nucleus, which is of course irreversible. This core or nucleus consists, in the first place, of certain operative patterns of the psychic mechanism, which may be regarded as constant not in the sense of being static but as representing a dynamic group of factors. How far these pathological tendencies of the psychic apparatus contribute towards the development of the related typical delusional ideas or psychomotor effects depends, within certain limits, on outside influences and hence also on a planned psychotherapeutic technique.

One might say such treatment is "only" symptomatic. The "only" is not, however, always appropriate in milder cases, since in our efforts in the realm of genetic biology we are quite exclusively concerned with the endogenous factor. But for the therapeutic result in the individual patient it can very well be decisive, whether a pathological factor develops into an outward symptom or whether it remains within the framework of an endogenous reaction tendency. This "only" can determine his fate; it can decide whether he will be socially incorporated or rejected.

All this becomes far clearer and more important when we leave the realm of the severe endogenous catastrophes and consider the milder borderline cases, the endogenously determined dislocations and variations of personality that are unaccompanied by psychosis. Consider, for instance, a schizoid psychopathy, one of the nuclear symptoms of which—autism—is manifestly rooted in the constitutional components of the personality. The intelligent young schizoid soon becomes aware of his peculiar inner sensitiveness, the resultant difficulties of establishing contacts, and his tendency to peculiarity; it becomes his problem in relation to himself and to the outer world. This problem is no longer endogenous but signifies a reactively determined psychic attitude. The personality becomes aware of its being different, it seeks form and adjustment. And at this stage psychotherapy can be of decisive help. Or it can depend whether the person finds his appropriate *modus vivendi et laborandi*, or whether he shrinks into himself to become a freakish eccentric. Similarly, increased difficulties during puberty are characteristic of the schizoid constitution; but whether or not he comes to grief in the collision with the parents is often decided by psychotherapy. Similarly there are certain appropriate kinds of milieu in which hypomanic or phlegmatic persons can lead constructive and productive existences; and, conversely, certain ways in which such persons can come to grief are determined by their constitution. Not the constitution in itself but the finding or not-finding of

* One of three lectures given at the Tavistock Clinic in April.

the appropriate milieu determines their destiny; and that is where psychotherapy comes in. It is a striking fact, discovered by Mauz in his work on epilepsy, that the clinically familiar explosive kind of epileptoid syndrome develops phenotypically chiefly among the lower social classes. The same endogenous disposition rarely manifests itself in that form among the educated classes; which means that the decisive symptom, the brutal explosiveness, fails to develop because it is inhibited by educational and environmental influences.

The Opposite Thesis

Now let us elucidate the opposite thesis: "Whatever has originated primarily as the result of external psychic stimuli must be regarded as curable by psychic means." But this thesis, too, is not so straightforward as is usually thought, especially in complicated, multidimensional formations. In the border-zones of schizophrenia or in non-typical depressions we encounter again and again individual cases which are precipitated by a severe psychoreactive shock and do not develop as a typical psychogenic disorder; instead, their course is governed in accordance with endogenous, constitutional dynamics; and once this process has been activated the way back to the psychogenic (exogenous) levels is finally lost. Similar observations can be made in the field of paranoia—for example, in the case of querulents whose illness was clearly reactively determined or in severe cases of pseudo-dementia of long duration, or again in those rare cases of prison psychosis which become chronic. In all these fields abnormal developments of personality occur in which the equation, psychogenic = responsive to psychotherapy, does not properly apply. In such cases the admittedly reactive origin cannot fully account for the resultant psychic disorder; or, at least, a dynamic disproportion becomes apparent between the swift and facile psychoreactive onset and the difficulties of resolution by psychotherapy.

Apart from these cases there still remains a psychotherapeutically unresolvable or hardly resolvable residuum, which can only be explained in terms of non-reversible processes in the endogenous structure of the personality. Such a process may take place before or after the onset of the psychic reaction. In the first case the psychoreactive formations grow in the soil of a personality which has already previously undergone an imperceptible progressive change; this may often be observed in paranoiacs. If we study the past history of such a querulent prophet or inventor, we may come across a slight warping of the developing personality round about puberty for instance—no destruction, no endogenous psychosis, but an imperceptible endogenous change. From now onwards the psychic machinery begins to run in a different gear. Affective dynamics, sense of values, logical appreciation—all these are somehow changed; claims between the ego and the outside world are somewhat differently evaluated. From now on there is a new endogenous foundation on which a new secondary personality picture begins to take shape; but this second picture is not a definite finished product of an endogenous revolution. It is only that new dispositions, new modes of response, and new workings of the psychic mechanism have been created, which in their turn immediately begin their reciprocal action with the stimuli of the outside world. It is only from this reciprocal action that gradually, in the course of years, a new development of the personality, a new picture of the personality, takes shape, which we may term paranoiac, a picture that reveals certain religious, sociological, legalistic, or technically constructive activities which could not be observed previously. Once this endogenous basis has been established extensive reactive effects of strong emotional experience and of stimuli of the outside world become possible, just as in any other person; and they produce symptoms and mould the personality. Thus a new structure of the personality can originate which is emphatically understandable trait by trait in its development and the psychogenic origin of which is perfectly apparent. Sometimes it also responds to psychotherapy. But it is not so easily reversible as its obvious psychogenic dynamics might lead us to suppose, for the underground working of the endogenous moiety of the personality—as seen with the eye of the normal person—is slightly perverted, which makes the psychotherapeutic approach more difficult and renders relapses more likely.

Conversely, the endogenous dislocation at the constitutional level can begin only after the psychic reaction. Pictures of this type are specially obscure in the construction of their symptoms; they are prognostically incalculable and ambiguous as to their inner causal relations. I am thinking, for instance, of a few rare cases of severe pseudo-dementia of long duration which I have occasionally come across and which are referred to in the older literature on chronic prison psychosis. They begin, for instance, after an accident entailing damages, or under the threat of criminal proceedings: massive hysterical pictures, not far removed from malingering; the relation of the content to the precipitating psychic situation, the decidedly psychogenic type of the affective-dynamic situation, and the tendentious coloration of the whole picture are very striking. Some cases of that kind do not remain fully psychoreactive: if one re-examines them years later the outward appearance is in the main almost unchanged, but it now produces a dull, petrified effect. The claim for compensation is maintained; but there is an absurd disproportion between the gain that can be anticipated and the severity and duration of the sacrifice of every form of vital interest. No longer can we detect a powerful inner reaction to a situation that has been tackled with hysterical vigour, nor the ingenuity of true malingering, nor yet the drive of genuine querulousness. Behind the hysterical façade we encounter a grave loss of vitality manifesting as hypochondria, a chronic loss of elementary drive and interest in work and recreation, such as no normal person could possibly simulate. There are cases among these which the critical observer can no longer fit into the framework of the merely "psychogenic" without his being able to detect the moment when the originally purely reactive picture changed its character or to specify the individual symptoms which constitute the change. We cannot say that at this point or at that point the hysterical reaction has been reinforced or superseded by an endogenous psychosis. Also we cannot say for certain what part causality plays as between the various factors. We can only say that behind an originally purely reactive disorder something else which is somehow connected with the endogenous vitality of the person has imperceptibly crept in. Finally, the divergence from the behaviour of an ordinary person in the same situation has become so great that it can no longer be fully explained even in terms of chronic hysterical habituation and facilitation. There are rare terminal pictures of this kind which make the patient appear no more capable of practical life than in the final stages of schizophrenia.

In view of their rarity the importance of such cases is not essentially a practical one. Their significance lies rather in the sidelights they cast on the dynamic principles of the human personality (in health and disease), and on

the intimate interplay of endogenous and psychoreactive forces. They also illustrate especially well the fluidity of the endogenous background of the personality throughout life, which, in psychic treatment, we too often forget in favour of an ostensibly rigid structure of the personality which is quite fictitious.

One could adduce instructive examples from the psychology of everyday life which reveal this interaction between psychic reactions to the outside world and vital losses of inner tension. If we consider healthy persons who have lived for a long time in forced seclusion, servitude, or in prison, we find that some of them are afterwards unable to find their proper place in a normal environment. It is said occasionally that they are "broken" in spirit. That is a sentimental expression, but it signifies something which is quite correct. The process, in fact, has a reactive origin, as a purposeful adaptation to an impoverished and oppressive situation, as a loss of "starch" in the personality, as a diminution of will and energy, as a limitation of interests and needs. One would expect that the personality, when relieved of the outer pressure, would spring back to its former position; but in some cases it fails to do so. Instead the patient finally exhibits a loss of vitality, a certain desolation and indolence which causes him to shrink in discontent from formerly valued activities. Similar pictures may be observed in persons who, without suffering from a serious physical illness, have been in receipt of a pension for many years which has spared them the struggle for life. When they lose this pension they are not only unwilling to work but sometimes lose the very ability to work: they have lost vital potentialities of activity which are never re-established.

A similar meaning attaches to popular phrases such as "to become soured," or "philistine." Dullness acquired in the long course of monotonous, unstimulating work, or by the atmosphere of a small town, occurs first as a reactive adaptation to the environment, which leads finally, through the co-operation of constitutional inner factors, to a definite loss of personal *élan*, which Möbius termed "physiological imbecility." Möbius believed that these phenomena only occurred in women, and in these soon after the termination of puberty. But, of course, the condition can be observed just as frequently in men if they are at all disposed towards it. Neither is the endocrine chemical process alone to blame, nor solely the "staleness" of professional life. Actually both are closely connected causally, and both together ultimately produce a changed attitude of the total personality, which then becomes unable to respond properly even to a change of environment, however stimulating. In other words, it has become unresponsive to psychotherapy.

What is Personality?

What we call a man's "personality" is merely a fictitious scheme which we can compare with what Schilder (dealing with the physical aspect) has termed "body schema." It is a schematic picture of the position, contours, and functional potentialities of its bodily parts which the ego necessarily visualizes, and which need by no means tally with the material facts and the neurological findings. Pain is felt and localized in the amputated limb just as if it still existed. In the same sense we can speak of the psychic side of a "personality schema."

The personality is not a real, tangible structure of constant properties, but a schematic abstraction of certain typical responsive tendencies, of a group of typical attitudes, trends, and vital aims which a person has hitherto generally exhibited and which one would expect him to exhibit in the future. Both the environment and the person himself contribute to this abstraction.

The fiction of a structural fixed personality has a certain real basis—namely, the hereditary disposition or psychophysical constitution and the manner in which it usually responds to fairly constant environmental conditions. The constancy of both factors, constitution and environment, is responsible for the approximate correspondence between the schema of the personality and reality. But if, for example, environmental conditions change, they can produce reactive potentialities hitherto unrealized in the character picture, and thus give rise to novel transient or permanent character traits. We have only to recall the enormous increase of hysterical reactions in the hospitals during the war, hysterical traits which for the most part would never have declared themselves in an ordinary environment. Conversely, we are reminded of the examples of great spiritual strength which is only evoked by danger or idealistic devotion in persons who are ordinarily shy and timid. One cannot say that the one quality is genuine, the other only fictitious. Both are constitutional reactive potentialities in one and the same person. They only become character traits, however, when they are evoked and maintained by appropriate environmental stimuli.

But in order to maintain the fiction of a static picture of the personality the environmental factor and the constitutional factor must both remain constant. Does not the conception of hereditary disposition and constitution already imply this constancy? What is constant is the germinal disposition, in so far as it includes potentially all behaviour patterns realized in the course of a human life. But they are realized according to the special laws of organism, and not simultaneously and not all permanently. Consider an alarm clock which is set to go off at a certain time; this is a typical example of potential energy which is present from the outset but is only realized for a moment. The same applies to many factors of the germ plasm. The hereditary constitution of a person may, for instance, be so set that at 18 years an attack of schizophrenia, or at 48 a bout of depression, is released. Hence germinal constancy is not the same as vital constancy. This is true not only of pathological hereditary factors but also of the ordinary so-called qualities of character. One cannot say that this man is energetic; we do not know whether he will be so to-morrow. This depends neither on illness nor on old age. In some people the fluid energy oozes away in the ordinary course of events, never to return. The careful observer will frequently be able to detect parallel constitutional fluctuations: changes of weight, of hair-growth, of skin elasticity, of potency.

The imperceptible developmental disorders and losses of vitality are, as soon as one begins to pay attention to them, of fundamental significance in relation to the origin of many neuroses and to the entire field of psychotherapy. So far, then, we can say that the personality schema is consistent, whereas the constitution is more fluid. In other words, the notion which the afflicted person has of himself, of his aims in life, and of his potential activities remains as it was in respect to the demands made on him by his environment. But the constitutional basis of this fictitious ego has slid from under his feet, unknown to himself. He now goes on attempting to respond according to his personality as it was hitherto—that is, within the schema of his formerly typical forms of adaptation to the outside world. At this stage a discrepancy arises between the real and the fictitious personality, together with a maladjustment to the outside world, which favours the genesis of neuroses. Here are a few clinical examples.

Conflict between Real and Fictitious Personality

A woman now 38 years of age wandered from one sanatorium to another, a severe case of hysteria with frequent fits, astasia, and a craving for operation. Formerly she had done social work, and had then gradually given up. Experiential complexes or outside difficulties cannot be considered as causal. On the other hand, the following was ascertained. Coincident with the onset of her hysteria she lost 23 lb. in weight. Judging by earlier photos, her habitus had changed from puffy and pasty to being markedly asthenic. Her hair became prematurely grey. The autonomic nervous system was found to be highly labile, her pulse feeble, and her muscles slack. Had the endogenous change in this woman taken the form of a massive bodily disease she would probably not have developed hysteria, just as the severely wounded soldiers seldom did in the war. The neurosis therefore has the purpose of revealing a genuine, and in this case grave, vital loss of tonus in body and psyche. But it is a loss of vitality which owing to its gradual, insidious nature is unable to fulfil the function which every acute disease immediately fulfils—namely, to act as a signal for the readaptation of the aims of personality in relation to oneself and one's environment.

Our therapeutic task in this case is essentially different from that which one is accustomed to consider as usual in hysteria. First, crude measures, such as simple disciplinary measures and forcefulness, are contraindicated. Attempts of this nature, which do not take into consideration the variation of the constitutional basis, would only tend to deepen the gap between the patient's will and her ability instead of bridging it. Experiential psychoanalysis would also fail, because here the difficulties are not experiential but biological. The treatment should aim at a reconstruction of the personality schema, which is no longer adapted to the new biological situation, and at finding the capacity for performance which is still compatible with the changed constitutional level.

Similar cases, incidentally, can occasionally be observed in women in professional life during and after the climacteric—for example, a partially genuine and serious loss of vital tonus of endocrine origin which takes the form of hysteria because it does not present a big enough front to the outside world. Here is another example:

A 40-year-old teacher was admitted for treatment with litigation mania and hysterical hypochondria. He had been waging a fierce struggle with the authorities and the villagers, who were alleged to be undermining his health and honour and conspiring against his life. Formerly he was a valued teacher and an energetic organizer who helped with youth movements and showed himself well able to battle with the world. The time when these normal conflicts became morbid and delusional coincided with a gradual change of his bodily constitution—namely, a considerable increase in weight with endocrine distribution of fat. His condition was greatly improved by endocrine and dietetic treatment combined with psychotherapy. For more than a year now he has again exercised his profession without disturbance.

Cases of this nature serve to illustrate most clearly the intimate interrelations between endogenous and psychoreactive factors in the personality. The schema of the combative organizing personality, which was well adapted to the original constitution, remains unchanged, whilst the serious constitutional endocrine-determined loss of vitality progressively saps more and more of its foundations. The patient still believes himself to be his former robust self, which he has long ceased to be. Owing to this discrepancy the healthy fighting man develops into the overexcited querulent.

Biological Fluctuations

Many of these biological fluctuations defy detection in the life of average persons because their mechanical routine work discloses little of their actual personality. On the other hand, one is surprised by the frequency and force of these inner changes of vitality in mentally productive individuals, since in their case every activity is borne by the full force of the personality and rises and falls with it. Thus the change from productive to unproductive periods produces a sort of "life curve" which can assume various forms, whether approximating to the undulant "circular type," as for instance with Goethe, or taking the schizophrenia-like form, as with Hölderlin and Uhland, in which a tense mental productivity in puberty is followed by a breakdown, or at least by a certain dryness and dullness. All this can well remain within the framework of biological variation, and need by no means assume the intensity of a psychosis. We can observe in many poets and research workers how some potentialities are only realized in certain, maybe very brief, phases of life remaining purely potential at all other times—inhibited for decades and then bursting forth all of a sudden; or early elation may be followed by utter exhaustion or, after a number of dry monotonous years, revived and pulsating periodically right up to old age. This can only be comprehended in terms of the fluctuations in the deep biological background of the constitution, which bears all outward developments of the personality in its wake and itself is changed.

Thus it can be shown how in the seemingly stabilized zenith of life in full swing, the personality can be affected in the absence of true disease or psychosis, by imperceptible shifts of its endogenous foundations, sometimes by favourable clarification, but sometimes by severe loss of substance. Every shift within what we have described as the constitutional radical of the personality—as, for instance, coloration of mood, impulse, stimulation, inertia—forces even the healthy person to a fundamental revision of his personality schema. When this is not possible on internal and external grounds, then there is always a possibility of psychogenic complications and of abortive attempts at pseudo-adaptation. Here, where the constitution changes and the environment remains constant, the danger of neurosis is just as great as in the far more obvious cases in which much altered environment acts on a constitution that has remained constant, as, for instance, in wars and catastrophes. In both cases the effect is the same—namely, the disturbance of adaptation between a constitution and its surroundings.

Critical Periods

What we have just described occurs most markedly and clearly in those phases of life at which every individual has his critical constitutional turning points; hence, above all, in puberty and during involution. Persons of thoroughly healthy constitution usually pass through these critical periods comparatively smoothly. In puberty, for instance, the psychic changes at the instinctive level harmonize with the process of physical maturation: the detachment from the parents: the gradual fusion of the individual components of the sexual impulse, its control and inhibition. On the basis of this instinctual metamorphosis the entire personality schema, with its performance, aims, ideals, and the demands of the environment, undergoes a parallel and harmonious reconstruction.

Every constitutional disturbance in the course of bodily maturation reveals to the careful critical observer corresponding irregularities in the instinctual metamorphosis. The individual psychosomatic signs of puberty become "asynchronized," no longer combine properly. This in turn results in discrepancies between the radicals and the personality schema, which manifest themselves as ambi-

valent attitudes of the youth towards the most important aims of life and the demands of the environment: again, a lack of balance within the personality and the environment. It is for that reason that disturbed and retarded pubescence gives rise to a number of neuroses in the post-pubertal period, especially between the ages of 20 and 30. I have dwelt on this on a previous occasion.

Conclusions

What bearing has this clinical approach on psychotherapy? The change is just as far-reaching as was that from the suggestive to the analytical method of treatment. At that time it was discovered that the suggestive removal of the neurotic phenomenon was merely a cure on the surface, because hidden behind the neurotic symptoms were emotionally toned experiences which had to be tackled therapeutically. The physician turned from the symptom to the experience. To-day we turn from experience to the personality. Without underrating the part played by certain powerful individual experiences, and, above all, the therapeutic value of an undogmatic experiential analysis, I and my collaborators have come more and more to regard individual experiences, both infantile and current, as only providing characteristic evidence, as though they were milestones marking the personality's path of development.

To-day we have come to recognize as essential the total structure of the personality and its relation to its surroundings *in toto*. Psychogenic tangles occur in the first place when the personality becomes disunited within itself or in relation to its environment—in other words, when the constitution and the personality schema, or the personality and the demands of the outside world, are in conflict. Thus the complicated psychological phenomena of neurosis are ultimately referred back to the clear clinical basis of our established fundamental concepts of natural science, to instinct and constitutional radical, to the problem of the struggle for life and adjustment to the environment.

The function of the physician in dealing with a patient suffering from a psychogenic disorder is therefore to study carefully his present-day constitutional make-up and personality structure in relation to all the significant conditions of his milieu, and to bring them to the consciousness of the patient sympathetically and truthfully. From the existing material, however rich or poor it may be, an in itself intelligible and genuine picture of the personality will have to be constructed and brought into a tolerable relation with the environment, which itself may require to be ameliorated by active interference on the part of the physician. Thus the biological adjustment—in other words, a new and tenable attitude to the struggle of life—is brought into being.

This biological approach can equally legitimately be made to apply to the psychic field. Only thus does the personality in itself acquire ethical value, and only through the elimination of sterile inner friction does it attain its highest efficiency in the service of the community.

The fifth Congress of the Societas Oto-rhino-laryngologica will be held at Bucarest under the presidency of Professor Metzianu on September 16, when papers will be read on indications for operation in acute and chronic mastoiditis, oto-rhino-laryngology in the medicine of to-morrow, a new method of radical operation in otitis media, and surgical diathermy in oto-rhino-laryngology. The subscription is 100 francs. Further information can be obtained from the general secretary, Dr. Chavanne, 5 Place des Cordeliers, Lyons.

THE CHEMICAL DIAGNOSIS OF EARLY PREGNANCY

A METHOD BASED UPON THE DETECTION OF OESTRIOL IN THE URINE

BY

JOCELYN PATTERSON, M.Sc., Ph.D.

Biochemist, Charing Cross Hospital

In a recent article in this *Journal* Crew (1936), when discussing laboratory tests for the early diagnosis of pregnancy, briefly indicated the need for a chemical test, and in mentioning some of the attempts that have been made to devise such a test commented upon their failure to provide trustworthy results. Two types of chemical reaction were specifically cited: (1) the histidine reaction, first introduced as a possible means of pregnancy diagnosis by Voge (1929); and (2) the Visscher and Bowman reaction (1933–4), the basis of which is somewhat obscure. The method of Schmulovitz and Wylie (1935) falls into a slightly different category from the above tests, because it is alleged to be based upon the chemical detection of the oestrogenic hormones which are known to be excreted in greatly increased amounts in pregnancy. It requires a great deal more urine than the other tests and a more complicated technique, but as it appeared to be developed from a sounder basis it was given a short trial in this laboratory. The method was abandoned, however, when it was found that the colours produced were not specific for the oestrin compounds, and, indeed, were far more intense than could possibly result from the hormone content of the extracts from which the colours were developed.

The New Method of Diagnosis

The method about to be described makes use of a similar basis to that which was theoretically adopted by Schmulovitz and Wylie. It is concerned, however, only with the oestriol content of the urine, the oestriol having been shown by Cohen and Marrian (1934) to be the predominating oestrogenic hormone in pregnancy urine, and present to the extent of five to ten times the amount of the associated oestrone. It utilizes, moreover, a more specific reaction for this hormone—namely, the Kober phenolsulphonic colour reaction, which has been so successfully developed by Marrian and his colleagues (1936) for the purpose of the rapid estimation of the oestrin compounds in late pregnancy urine, and also as a guide to their isolation of oestriol glycuronide from the same urine.

Having had considerable experience in the use of this reaction upon extracts from late pregnancy urines, I have attempted to adapt it to early pregnancy, where the amount of available oestriol was of course very much less and the proportion of interfering substances correspondingly greater. As Marrian has shown, the oestriol of pregnancy urine is present in the form of a compound with glycuronic acid, and before the active hormone can be isolated the conjugated form has to be broken down by drastic acid hydrolysis. This preliminary hydrolysis has the effect of markedly increasing the pigmentation of the urine, and certain dark products cannot be wholly eliminated in the course of working up the extracts for the oestriol reaction. In the final stage they give a darkish-brown coloration to the Kober reagent, which in early pregnancy urines completely masks the character-

istic pale red due to the presence of minute quantities of oestriol. Failure to effect sufficient purification of the extracts of these acid-hydrolysed urines by any simple means led to the examination of other methods of accomplishing the breakdown of the glycuronide that would not at the same time introduce such complications as those referred to. Marrian in his work on the hydrolysis of the oestrin compounds showed that the release of the active hormone could also be accomplished by incubation of the urine for fourteen days, thus producing a high degree of putrefaction. As only a relatively slight increase in pigmentation accompanied this putrefactive process it was decided to find out whether the breakdown could be brought about rapidly by utilizing heavy inoculation of the urine with *B. coli* and limiting the incubation period to sixteen hours (or overnight). At first urines containing a great deal of oestrin were examined—namely, those from the later stages of pregnancy—and it was found that the amount of oestriol as ascertained by colorimetric means in extracts from such urine treated bacteriologically was fairly comparable with that in parallel extracts obtained after initial treatment by the Marrian technique of acid hydrolysis.

Two samples were then compared in strictly quantitative manner with regard to the oestriol fraction only, adopting the method of Cohen and Marrian for application to both acid-hydrolysed and bacteriologically treated portions. The results were as follows:

Sample	Acid-hydrolysed	Bacteriologically Treated
	mg. oestriol per 100 c.cm.	mg. oestriol per 100 c.cm.
I	0.77	0.59
II	0.58	0.47

Though these results showed the bacterial hydrolysis to be rather less efficient than the acid hydrolysis, the final extracts from which the colour reaction was developed were entirely colourless in the case of the former procedure, whereas in the other they were a slight brownish yellow, such pigment interfering with the colour tone of the pure oestriol reaction. From the point of view of colorimetric estimation the extracts from the urine treated by bacteria were therefore much more satisfactory. It was obvious that the amount of splitting by the bacterial hydrolysis was sufficient to warrant its trial in the detection of oestriol in the urine in the earliest stages of pregnancy.

From the beginning the results were distinctly encouraging, even on such relatively small quantities as 50 c.cm. of urine, and only occasionally was difficulty encountered in the preparation of satisfactory extracts. Originally the urine after incubation was acidified to Congo-red, then treated with 20 grammes of ammonium sulphate, preparatory to the ether extraction of the hormone. Later it was found that the final extracts were uniformly better if both acidification and ammonium sulphate were dispensed with and direct extraction was made with ether. Even then, however, there was occasionally a trace of contaminating pigment capable of yielding a brownish yellow in the oestriol colour reaction, and this was eventually eliminated by a preliminary treatment of the urine with sodium bisulphite, which reduced the original pigment of the urine by about 50 per cent. and led ultimately to the production of a final extract, which contained practically no interfering substance in the last stage of the test. The detailed technique as finally adopted is described below.

Technique

Urine Sample.—The requirement of the test is a sample of at least 50 c.cm. of early morning concentrated urine, collected into a vessel chemically clean in the sense of being entirely free from all substances which might be inhibitory to bacterial action. It is also advisable that the patient should not have had any drugs for a few days before the collection, for these often increase the pigmentation of the urine, and may also adversely affect the preliminary bacterial hydrolysis.

Preliminary Treatment.—The urine is tested for high acidity by treating a few drops with methyl-red, and if acid to this indicator is adjusted with addition of alkali until it no longer shows a pink colour. A 50 c.cm. sample is then heavily inoculated with *B. coli* and incubated overnight. To the urine after incubation, whilst it is still warm, is added approximately 0.5 gramme of sodium bisulphite. The specimen is shaken until the solid has completely dissolved and then allowed to stand for fifteen minutes.

Extraction.—The partially decolorized urine is transferred to a separatory funnel of about 150 c.cm. capacity and extracted with two lots of 40 c.cm. of ether. Occasionally some emulsification occurs, but this may be rapidly resolved by centrifugation. The combined ether extracts are washed with a little water, and then well shaken with a 30 c.cm. portion of 10 per cent. sodium carbonate. The alkali layer having been discarded, this washing process is repeated until the carbonate layer is completely colourless. The ethereal solution is then again washed with distilled water, and when the water layer has been drawn off the ether layer is further extracted with two lots of 40 c.cm. of N/10 sodium hydroxide. After separation and rejection of the upper ethereal solution the combined alkali portions containing the oestriol are treated with 25 per cent. sulphuric acid drop by drop until acid to Congo-red paper. This acidified aqueous solution is then extracted with two portions of 40 c.cm. of pure "analytical" ether, after which the ether layers are combined and washed with a little water. The ether extract is given another washing with 10 per cent. sodium carbonate, and after the rejection of the alkali the remaining ether is freed from all trace of the alkaline carbonate by two more washings with distilled water. The final clear, colourless ether solution is next transferred in two portions to a 50 c.cm. transparent silica flask and the solvent completely evaporated by immersing the flask in a large beaker of water previously heated to 70° C.; the last traces of moisture are then removed *in vacuo* by direct application of suction to the flask. The dry residue is now ready for the development of the colour reaction, using the phenolsulphonic reagent.

The Reagent.—The reagent used is that recommended by Cohen and Marrian, and consists of 3.6 parts of pure phenol with 5.6 parts of pure concentrated sulphuric acid. Small quantities only are prepared at a time; 9 c.cm. of phenol, liquified by heating, to which are added 14 c.cm. of sulphuric acid with sufficient external cooling to the container to prevent undue rise of temperature, makes a convenient amount. It can then be stored in a 25 c.cm. all-glass burette, fitted with a ground-glass stopper so as to exclude moisture from the reagent. Considerable care must be taken with the reagent, which is very hygroscopic and becomes inactive when it takes up water. In measuring out, therefore, it is important first to discard a volume equal to that portion in the tip of the burette below the stopcock, so that only completely protected reagent is used

for the reaction. Moreover, it is advisable only to use a reagent which is less than one week old.

Colour Reaction.—To the flask containing the dry residue 1 c.cm. of reagent is added from the burette, and the flask then immersed in a large water-bath previously heated to about 70° C. By frequently rotating the flask the whole of the residue distributed round the sides is brought into the reagent, and the temperature of the bath is rapidly raised to boiling point, and kept there for a period of exactly ten minutes. During the boiling period it is again advisable from time to time to rotate the reagent round the sides of the flask. The reagent at this stage has assumed a yellowish colour, and it is now cooled by holding the flask under a stream of tap-water. While this cooling process is going on 1 c.cm. of 5 per cent. sulphuric acid is slowly added, the contents of the flask being kept moving in order to bring the somewhat syrupy reagent into a homogeneous solution with the dilute acid. The product, which is still yellowish, is then reheated in the boiling-water bath for a period of two and a half minutes. A positive reaction is obtained when the original colour gradually changes over to pink or red; a negative when this change is entirely absent.

Results

Altogether sixty-five cases have been tested by this method, not including any of those which were examined in the course of the preliminary work leading up to the adoption of the above technique. In all cases the urines were those submitted for pregnancy diagnosis, so that in no instance was pregnancy established beforehand by clinical examination. The first sixty-three cases have been divided into three groups, and the results are recorded in relation to the time elapsing since the first missed period, where that information is available.

GROUP I.—*Twenty-two Cases in which Pregnancy was Established by the Friedman Reaction, and in which Clinical Details were Furnished with the Specimen, so that the Duration of the Pregnancy could be Determined*

(a) Period 2 weeks overdue	.. ..	6 cases
Positive	.. ..	5 „ (all reactions were weak)
Doubtfully positive	.. ..	1 case
(b) Period 3 weeks overdue	.. ..	6 cases
Positive	.. ..	5 „
Weakly positive	.. ..	1 case
(c) Period 4 weeks or more overdue		10 cases
Positive	.. ..	10 (all fairly strong)

GROUP II.—*Eleven Cases in which Pregnancy was Excluded by a Negative Friedman Reaction, and in which Similar Clinical Information was Supplied to that given in Group I*

(a) Period 2 weeks overdue	.. ..	1 case
Negative	.. ..	1 „
(b) Period 3 weeks overdue	.. ..	3 cases
Negative	.. ..	3 „
(c) Period 4 weeks or more overdue	..	7 cases
Negative	.. ..	7 „

GROUP III.—*Thirty Cases Submitted with no Clinical Details*

(a) Pregnancy established by the Friedman reaction .. 18 cases

Oestriol reaction { Positive, 16; Doubtfully positive, 1; Negative, 1

(b) Pregnancy excluded by a negative Friedman reaction, 12 cases

Oestriol reaction .. .. Negative, 12 cases

Since completing the above series two cases became available which gave positive Friedman reactions at a stage when the period was only one week overdue. These were submitted to the chemical test, and one gave a weak but easily recognizable reaction, while the other gave a much stronger positive, comparable to that usually obtained in Group I (*b*).

In the whole series there is only one error arising from the application of the chemical test to early pregnancy diagnosis, so that its accuracy can be said to approach that of the Aschheim-Zondek and Friedman tests. Two cases of doubtful positivity, however, would have required repetition one week later, while, on the other hand, one Friedman test had to be repeated because it gave a very doubtful reaction when the colour test showed a definite positive. The second biological test on a further sample obtained five days later confirmed the accuracy of the chemical diagnosis.

Most of the other tests that have been suggested as a means of pregnancy diagnosis have had the merit of simplicity without that of reliability. With this test the reverse holds, and it leaves something to be desired by way of simplification. However, investigation has shown that none of the steps can be sacrificed without impairing the general efficiency of the process; the only saving that might reasonably be resorted to would be to cut down to a single extraction, using about twice the volume of the extracting medium, those processes where two extractions have been adopted as the standard practice. If consideration, therefore, be made only of the time and labour involved in a single test, then it becomes doubtful whether such technique could find general application to pregnancy diagnosis. However, where larger numbers are concerned and measures are taken to carry out five or six tests simultaneously, the method warrants more serious consideration as a practical alternative to the biological methods. To carry out such simultaneous extractions all that is necessary is the construction of a mechanical shaker to hold a number of separatory funnels.

Advantages and Disadvantages of the Method

At this stage one may conveniently summarize the advantages and disadvantages of the chemical method as compared with the biological tests. In favour of the former it can be pointed out that it enables a result to be obtained in twenty-four hours, whereas the most rapid of the biological tests usually takes forty-eight hours. It dispenses with animals, the upkeep of which is expensive and which are subject to marked individual variation in sensitivity to hormone injection. Moreover, it can make use of specimens that have undergone some degree of putrefaction and have become toxic to test animals.

Its disadvantages are: first, the more laborious technique, and, secondly, that the reactions are rather weak at the stage when the period is only two weeks overdue. There is also the possibility that the chemical test may be, in general, a few days behind the Friedman test in providing positive results in the very earliest stages of pregnancy. This point, however, has not as yet been sufficiently investigated.

Even though, owing to its more tedious procedure, the method might not be adopted as a routine in pregnancy diagnosis, the very fact that it provides a much readier route to the approximate determination of excess of the preponderating oestrogenic hormone than that by way of biological assay would seem to assure to it (or perhaps some slight modification adapted to larger quantities of urine) a role of some practical importance in the field of endocrinology.

Summary

1. A biochemical test for the diagnosis of early pregnancy is described which is based upon bacterial splitting of oestriol glycuronide and the subsequent development of the oestriol colour reaction with phenolsulphonic acid.

2. Urines from sixty-five cases in which pregnancy diagnosis was required have been examined by the test. In all except one case the result was in agreement with that of the Friedman reaction. The advantages and disadvantages of the test as compared with the biological tests are briefly discussed.

In conclusion I have to express my warmest thanks to Messrs. Parke, Davis and Co. for a generous supply of pure crystalline oestriol (theelol), which has been used in this work as the standard control substance. My thanks are also due to Miss I. McPhee for her invaluable assistance in the carrying out of the many extractions, and to Dr. A. R. Berrie and Mr. T. Harvey of the bacteriological department, who kindly undertook the inoculations.

ATHLETIC INJURIES OF THE KNEE-JOINT, EXCLUDING CARTILAGE INJURIES*

BY

W. E. TUCKER, B.Ch., F.R.C.S.

Orthopaedic Surgeon, London Homoeopathic Hospital

Of all athletic injuries those of the knee-joint are the most common. They often lead to prolonged unnecessary incapacity and absence from sport, especially if no definite programme of treatment is mapped out from the start. The athlete is usually a sane and sensible person as regards carrying out the treatment of his injuries, provided that the diagnosis, the difficulties of a quick recovery, and an active course of treatment in which his full co-operation is necessary are fully explained to him. Athletic injuries to this joint, as in all other injuries, may be due to: (*a*) direct violence, or (*b*) indirect violence.

Direct violence, such as a fall on the knee, a knock, or a kick, may cause any of the following:

1. A traumatic synovitis.

2. Contusion of the quadriceps muscles or their expansions. In these cases a synovitis of the knee may follow in a few days, either from seeping of blood serum into the joint or irritation of the capsule and synovial membrane by the products of bruising. Efforts are naturally made to prevent this synovitis, but the patient is warned of its possible occurrence.

3. A prepatellar bursitis or bruising of the infrapatellar pad of fat.

4. Fracture of the patella or head of the fibula.

Therefore in cases in which there is tenderness in relation to a bone a radiograph should be taken immediately.

There are four main types of indirect violence:

1. Flexion, usually producing a synovitis.

2. Rotation, which in a mild degree produces a synovitis, but if severe causes cartilage injuries.

3. Lateral wrenches, in which the lateral ligaments are involved.

4. Extension, in which the anterior cruciate ligament, infrapatellar fat and alar folds, as well as the posterior capsular structures, including the popliteus tendon, may be damaged.

* Read in the Section of Orthopaedics, including Treatment of Fractures, at the Annual Meeting of the British Medical Association, Belfast, 1937.

Often the injury is due to a combination of two or more of the above.

Before considering in detail each variety of injury let me here stress the importance of giving the patient special instructions as to graduated remedial exercises and simple remedies which he can carry out himself. The patient is warned that at all costs he must avoid undue wasting of the quadriceps muscles and a stiff knee. A scale of graduated exercises starting with those avoiding weight-bearing includes:

1. Twitching and contracting the quadriceps muscles for two minutes every hour while lying on a couch.

2. With the legs dangling over the edge of a couch so that the knees are bent, alternately extending and flexing each knee. This exercise is carried out twice daily, starting with twenty complete movements, increasing by five movements each time.

3. Raising the extended leg by flexing the hip while lying flat; abducting the thigh at the hip and then adducting it. This exercise is designed to bring into action every muscle of the thigh and buttock.

4. Bicycling.

With each exercise the patient should be made to relax completely before starting the movement again, as it is the active contraction of the muscle from its completely relaxed state which is so important. As the patient improves and synovitis disappears graduated weight-bearing exercises can be started—such as:

5. Holding the back of a chair; heel raising and knee bending and straightening.

6. Skipping.

Simple home remedies include:

1. Sponging the knee alternately with hot and cold water, thirty seconds of each for five minutes.

2. Massaging the muscles above the joint with olive or castor oil.

3. The application at night of Scott's dressing, antiphlogistine, or lead and opium.

Let us now consider the various injuries in detail.

Internal Lateral Ligament Strains

The importance of having a clear outlook on these injuries cannot be emphasized too strongly, as they are one of the commonest causes of chronic knee complaints. The injury is caused by an abduction wrench such as takes place in turning while ski-ing, and is so common in Switzerland that it is vulgarly known as the "Swiss kiss." Sometimes rotation occurs in the injury, and an injury to the internal semilunar cartilage complicates the condition. This complication one might expect in mining injuries, but it is my experience that in athletic injuries it is uncommon for internal lateral ligament strains to be associated with cartilage injuries. In those cases though, in which the maximum tenderness is at the middle of the ligament, at or near the point of attachment of the internal cartilage to the deep surface of the ligament, and in which there is limitation of full extension from the start, damage to the cartilage should be considered as a likely complication of the strain.

Usually, however, there is marked tenderness at either its upper or lower attachment—the upper is more common—and external rotation is limited and painful. Sometimes a small flake of bone is separated from the attachment of the ligament to the internal femoral condyle. It is important, therefore, to radiograph all cases at once. The essential point to be sure of is whether extension is limited or not. In the early stages of an uncomplicated

internal lateral ligament strain we find that extension is not limited. In untreated cases, and in those in which no effort is made to prevent limitation of extension, it will be found that after a week the last five degrees of extension becomes limited and painful. This is due to the fact that injured ligaments always tend to shorten—a pathological principle which at present is apparently not properly understood. Otherwise so many of these cases would not be treated by supporting the ligament in its relaxed position—that is to say, in the case of the internal lateral ligament, supporting the knee in a slightly flexed position. The strong flexor group of muscles, already tending to flex the knee, have thus an added mechanical advantage, and fix the joint by spasm. If this position is maintained for long, secondary contracture of the ligament takes place, due to the formation of granulation tissue in and around it, especially between the ligament and the joint at the back.

For the sake of treatment and prognosis I shall classify these strains in three degrees—mild, moderate, and severe. As a general working rule, even with intensive and properly directed treatment, mild degrees will take at least six days to recover completely, so that the patient is able to carry out full exercises. Moderate degrees take six weeks and severe degrees six months.

Treatment of Mild Degrees

Heat and massage over the ligament and surrounding muscles are started at once. A tendency will be found for the products of bruising to spread down the ligament and around the muscles at the back of the joint. The quadriceps are stimulated by graduated faradic contractions for twenty minutes daily from the beginning, and the constant extension of the knee by these contractions helps to prevent the tendency towards slight flexion of the joint. Gentle daily manipulative movements concentrating on the involuntary joint movements, such as moving the patella from side to side, the tibia forwards on the femur, and rotatory movements within the limits of movement without pain, while tension and countertension are applied, are of great value in that they overcome the spasm of the muscles strapping the inner side of the knee. In addition anodal galvanism or diathermy can be given.

Treatment of Moderate and Severe Cases

Skiagrams may reveal a small flake of bone detached from the surface of the internal condyle, or rupture of the ligament may be suspected by undue lateral mobility of the joint. The knee should be placed in a plaster-of-Paris cast in full extension for a period varying from three days to three weeks according to the degree of injury. A pad of felt is first placed over the length of the internal femoral condyle and the ligament. The cast consists of a back plaster holding the knee in the fully extended position and maintained by two plaster bandages, one above and one below the knee. A third bandage is wound round the knee in a figure-of-eight so as to exert lateral pressure over the pad of felt and the internal lateral ligament. Care is taken to leave the patella free, so that this can be moved from side to side and up and down daily. There is ample space above the top of the plaster in which to stimulate the quadriceps by faradism daily. Unless there is a rupture of the ligament or separation of the flake of bone weight-bearing is allowed and the patient encouraged to contract the quadriceps voluntarily. In this way traumatic effusion is massaged away from the ligament by the firm pressure pad, the tone of the quadriceps is helped, and full extension is maintained.

When the plaster is removed, and for a varying period afterwards, flexion of the knee may be markedly limited and painful, but this will gradually return with remedial exercises, faradic contractions, massage, and gentle manipulative movements. No forced movements should ever be attempted, and a manipulation under an anaesthetic is only justifiable as: (*a*) a diagnostic procedure to rule out an associated misplaced cartilage; and (*b*) in cases of several months' standing, in which all tenderness has disappeared from over the ligament and it is felt that any limitation of joint movement is due to formation of adhesions. Early forcible manipulation in these cases will often only give rise to disappointment and aggravation of the condition. As soon as walking is allowed the tread and heel of the shoe should be raised a quarter of an inch on the inside to prevent strain on the ligament.

Patients with a moderate degree of sprain treated for a short period in plaster have returned to football two weeks after the injury. Comparison with untreated cases and with those treated by other methods show their recovery period to be about one-quarter as long. Severe strains complicated by separation of a flake of bone or rupture of the ligament do take a long time, but recovery is helped by periodic courses of diathermy and faradism. Massage is not given in these cases over the ligament or condyle.

External Lateral Ligament Strains

These are often associated with sprains of the biceps tendon, ilio-tibial band, and external quadriceps expansions, and frequently are due to direct injury. Swelling appears on the outer side of the knee in connexion with the biceps tendon and insertion of the ilio-tibial band and external quadriceps expansion into the external tibial condyle, and is often mistaken for a cystic condition of the external semilunar cartilage.

Treatment consists of heat, massage, graduated faradic contractions, and gentle manipulative movements, to which may be added anodal galvanism or diathermy. Radiographs should exclude a crack in the head of the fibula.

Bruising of Infrapatellar Pads of Fat and Alar Folds

These may be caused by hyperextension or direct violence and give rise to swelling and tenderness below the patella and on each side of the ligamentum patellae. There is limitation of full extension and pain on coming downstairs. Owing to early wasting of the quadriceps often a vicious circle is started, as weakness of the crureus and subcrureus allows further pinching of these structures by not pulling them from between the joint surfaces in full extension. Treatment should consist of deep massage over the pads combined with faradic contractions and anodal galvanism or diathermy with the terminals arranged in an antero-posterior direction.

Often violent hyperextension is associated with strain or rupture of the anterior cruciate ligament and the posterior capsular structures, including the popliteus tendon. If a strained or ruptured cruciate ligament is suspected, as shown by undue forward mobility of the tibia on the femur, the knee should be put in plaster for three weeks—weight-bearing is not allowed, but during this time the quadriceps are treated with faradism. If the structures at the back of the joint are strained the treatment should be divided between the front and back of the joint, and heat, massage, and faradic contractions should be given to the gastrocnemii, popliteus, and hamstring muscles as well.

Synovitis

I have left synovitis to the end intentionally, as it is often a complication of all the preceding conditions; naturally, if present, it should be treated first.

Aspiration of the joint, especially if the effusion be partly haemorrhagic, which it usually is, will give instantaneous relief. Under strict aseptic technique the outer side of the suprapatellar pouch is anaesthetized with 2 c.cm. of 2 per cent. novocain or novutox. Through this anaesthetized area a small scratch is made with a tenotome and a large-bore needle is pushed into the joint and the synovial effusion aspirated. There is no risk attached to this procedure provided it is carried out under conditions of strict asepsis, and it will prevent granular lumps of inspissated blood collecting in the suprapatellar pouch. It is these which so often give rise to adhesions and chronic capsulitis with marked quadriceps wasting. As a result of aspiration and the use of a local anaesthetic there may be slight pain in the joint after about four hours, but by the next day this has passed off and the condition has eased. A slight return of effusion may be expected, and as long as this persists weight-bearing should be avoided, since the synovial membrane is so sensitive and inflamed at this stage that any weight on the joint is apt to produce more effusion and swelling.

As soon as the joint has been aspirated pressure is applied by a firm bandage over lint or wool soaked in lead and opium. The next day treatment consisting of heat, massage, faradic contractions, and gentle manipulative movements is started. If the amount of effusion is small and aspiration is not considered necessary anodal galvanism or diathermy may be added.

The length of time in recovering will vary according to the severity of the synovitis—from a few days to a month—but even the severest degree of traumatic synovitis should have completely cleared up in this time, provided there is no complication such as a lateral ligament strain or cartilage injury. Slow recovery should arouse suspicion of some underlying septic focus, and the patient must be carefully examined to exclude this.

Chronic Knee Strain

There is a type of strain which appears frequently in middle-aged and overweight patients, often following prolonged exercise, such as thirty-six holes of golf or a long day's shooting. Sometimes patients give a history of an old injury to the joint, or the *x* rays may show slight early osteo-arthritic changes. Synovitis is present, the quadriceps are atonic, and the extremes of joint movements may be limited.

Treatment consists of heat, massage, graduated muscular contractions, and the limitation of active exercise until movements and muscle tone return to normal. These cases usually clear up completely at the time, but often tend to relapse and require further treatment some years later. If they are neglected synovial changes occur, the muscles waste further, and definite osteo-arthritis of the joint sets in.

Quadriceps Insufficiency

This condition has long been recognized as a common cause of recurrent synovitis or of an unstable knee. Very often this type of knee is labelled as due to a torn cartilage, but is no better after the cartilage has been removed, since the cause of the condition has not been corrected. Quadriceps insufficiency should be divided into three types, and each type gives rise to different symptoms:

1. Vastus Internus Insufficiency.—Pain and a strained feeling are felt on the inner side of the knee.

2. Crureus and Subcrureus Insufficiency.—Symptoms are referred to the infrapatellar pads and alar folds.

3. Vastus Externus Insufficiency.—This is often associated with a slack ilio-tibial band. Pain and instability of the outer side of the joint may lead to the diagnosis of a damaged external cartilage. Careful examination will reveal in which part of the quadriceps there is most wasting, and every endeavour must be made to correct the wasting by graduated faradic contractions and special exercises.

Frequently quadriceps insufficiency is associated with limitation of movement. If this be so the joint must first be manipulated under full anaesthesia, followed by daily routine treatment. A joint may apparently be free in movement but painful on playing football or running full out. This type of joint is often completely cured by a forcible manipulation.

Conclusion

I will end by stressing the following points:

1. Severe internal lateral ligament strain takes a long time to recover and treatment cannot be forced.

2. Quadriceps insufficiency may be divided into three parts—inner, middle, and external.

3. Remember that Sir Robert Jones emphasized the importance of trying the effect of forcible manipulation on a knee-joint before labelling it functional or before removing a doubtful cartilage injury.

4. Always give the patient remedial exercises to carry out. He then feels that he is taking an active part in his own recovery.

Clinical Memoranda

Expulsion of a Placenta Praevia in Advance of the Foetus

A careful search of the literature has elicited only four references to the expulsion of a placenta praevia in advance of the foetus. On the Continent Magnani (1931), Laviano (1932), and Cambon (1935) have each recorded a case, while in this country Petch (1924) gave details of a case he encountered some thirteen years ago. The last-mentioned, on arriving at his patient's bedside in response to an urgent summons, found the whole placenta lying in the bed and the foetus evidently not yet born. Examination showed that the foetus was occupying a transverse lie. Though the expulsion of the placenta had apparently been preceded by a heavy loss of blood, the patient's condition was good enough to permit of internal version and the pulling down of a leg under anaesthesia. She made a satisfactory recovery.

The placenta in the case which came under my care, and the details of which follow, was noticed, though not recognized as such, by me in process of extrusion, and a minute or so later was seen and recognized without difficulty lying in the bed. I was engaged in washing up in the intervening moments, and I therefore was not actually a witness of its complete birth: but there was certainly a minimal loss of blood accompanying the process or, for that matter, following it.

CASE HISTORY

Mrs. S., aged 29, had had one normal confinement at home in 1931, and a second, also normal, at home in 1934. She had booked a midwife for her third confinement, which was expected to occur in March, 1937, and had not consulted her doctor at all, as she had been in very good health. In the first week of January, 1937, when the pregnancy had reached twenty-eight weeks, a sudden profuse haemorrhage occurred one night, waking the patient up and causing her considerable alarm. By the morning the loss was so small that the patient, though conscious of weakness, did not notify her doctor of what had happened. A fortnight later a second and still more severe haemorrhage occurred, again during the night. This time it was so persistent that the patient, feeling that she could not continue to lose so heavily, sent her husband to the doctor, asking him to arrange for her immediate transfer by ambulance to hospital.

When, therefore, the patient arrived at the hospital in the early morning in a more or less moribund condition she had not been examined by her doctor (by the time he was sent for vaginal examination was contraindicated by the patient's condition and his only course was to act as he did) and was too near death to stand the careful examination necessary to diagnose placenta praevia per vaginam, apart from the danger of aggravating haemorrhage by such a procedure. Abdominal examination revealed only a vertex presentation. Attention for the time being was given entirely to the treatment of the patient's grave general condition. The pulse on admission was almost imperceptible and uncountable, the patient semi-conscious, the respirations sighing, and the skin covered with a cold sweat. The house-surgeon whilst awaiting my arrival gave an intravenous saline with marked improvement in the pulse.

Guided by the lack of any evidence of toxaemia, no oedema, only a slight trace of albumin in a catheter specimen of urine, and by the nature of the haemorrhage—sudden, profuse, and whilst at rest in bed, in an otherwise healthy woman—on my arrival I diagnosed this as a case of placenta praevia.

The pulse rate now was 160 and the patient obviously in a very critical condition from extreme exsanguination. Blood was still trickling slowly from the vagina. Occasional but definite labour pains were occurring, causing further distress. Morphine 1/6 grain was given hypodermically. Arrangements for a blood transfusion were made by the kind co-operation of my colleague Dr. Vaughan Facey, and in the meanwhile a further intravenous saline was given.

It was then that during a pain I looked to see whether there was any further loss per vaginam. Actually I saw the vagina distended by what I took to be a large bag of waters covered with blood clot. I washed up; and on my return to the bedside found the whole placenta lying between the patient's legs. The umbilical cord, as it passed back through the vagina was covered by the membranes, while the maternal surface of the placenta was exposed. The placenta was evidently the object which I had seen in process of expulsion, maternal surface foremost. Its expulsion was not preceded or followed by any increase of haemorrhage.

The blood transfusion was then carried out, and the general condition of the patient, who was now able to take hot drinks, improved visibly. Two hours after the expulsion of the placenta the foetus was born by the vertex easily and without further loss of blood.

The puerperium was complicated by the development of a rather extensive thrombophlebitis of the left leg, but in due course the patient returned home in good health.

J. W. NANKIVELL, M.B.Lond., F.R.C.S.Ed.
Assistant Obstetric and Gynaecological Surgeon, Royal Victoria and West Hants Hospital.
Bournemouth.

Reviews

CLINICAL PATHOLOGY

Clinical Laboratory Diagnosis. By Samuel A. Levinson, M.S., M.D., and Robert P. MacFate, Ch.E., M.S. (Pp. 877; 144 figures, 13 plates. 45s. net.) London: H. Kimpton. 1937.

There is no dearth of "bench-books" designed as a guide to the examination of morbid material, and any new work of this kind, apart from the ephemeral advantage of being fully up to date in a constantly expanding subject, is likely to depend for success on some new feature or method of presentation. Levinson and MacFate's *Clinical Laboratory Diagnosis* differs from many similar books in being widely comprehensive both in aim and in presentation; it is a practical textbook on chemical pathology, haematology, bacteriology, and parasitology, and even toxicology, and thus provides information on every kind of procedure likely to be necessary in examining pathological specimens. The main chapters deal each with one of the body fluids and with its examination from all these standpoints, and each concludes with a description of the principal diseases in which abnormal findings may be expected. Technique is fully described, including the composition of all reagents used. Other chapters deal with skin tests, the special procedures required and the differences in results to be expected in children, milk and water examinations, histological technique, the detection of poisons, and a complete programme for conducting a class in clinical pathology.

As a book of reference providing instruction in methods with which the worker may be unfamiliar this will be of great value. As a general guide in education or routine work it may be found to have certain disadvantages. On the all-important question of interpretation, and in particular on the difficult decision whether given cytological and bacteriological findings indicate the existence of infection, much more might have been said, and to the same end a chapter on the normal body flora would have been helpful. There is also what may be called a rule-of-thumb tendency which we deprecate; why, for instance, should it be laid down in the table of appropriate culture media on page 547 that material from certain parts of the body, including the throat, eye, and peritoneal cavity, should be cultivated in a medium containing brain? The choice of medium depends, not on the source of the specimen, but on the infection suspected. The list of "Common Infectious Diseases and the Causative Organisms" in the same chapter illustrates the same attitude; two bacteria in each case are given as the common causes of asthma, bronchitis, empyema, acute endocarditis, and pericarditis; while to include headings such as abscess, inflammation, and ulcer in this list, following them with the mention of one or two common bacteria, serves no useful purpose. This section includes statements that "duodenal and gastric ulcers are due to streptococci" and that "mycosis intestinalis" is caused by *Bacillus anthracis*. The besetting sin in clinical pathology is the too ready attribution of disease to bacteria of doubtful significance, as in the former statement, and the general adoption of a much more critical attitude is highly to be desired. This criticism does not detract from the value of the book as a technical guide, and we can commend it as a source of information otherwise only to be obtained from works on several different branches of applied pathology.

DIET FOR DIABETICS

Diets and Recipes and the Treatment of Diabetes and Obesity. By E. P. Poulton, M.A., D.M., F.R.C.P. (Pp. 121. 7s. 6d. net.) London: H. Milford, Oxford University Press. 1937.

Dr. Poulton has written a book full of practical facts and food tables which he has found useful in the treatment of diabetes. The book is almost entirely concerned with diabetes, and diet in obesity is dealt with far too shortly in only two pages. The author uses high carbohydrate diets with moderate protein and fat and advocates the total weighing of the diet. In diet arrangement he has created a "carbohydrate ration" of 20 grammes carbohydrate, and uses varying ratios of carbohydrate to fat of from 1 to 2 to 6 to 1. His fat ration contains 10 grammes of fat. But in both C. and F. food values he also gives lists of half rations. These two different "rations" seem unnecessary and are apt to confuse, because anyone who is capable and likely to weigh his diet is also able to multiply or divide by two. Thus one single "ration" of C. and F. would be less confusing.

The recipes are extremely well arranged and indexed, and ought to be very welcome to patients. (They have been published separately under the title *Diets and Recipes* by Milford at 1s. 6d.) Useful chapters on vitamins and mineral metabolism are also included. The footnote on page 76 is rather surprising and its meaning obscure. In Table 8 bovril and oxo have been included, quite rightly, among articles of "negligible food value," but the footnote apologizes for this and says that "extras of small calorie value" is a better description. Why, we wonder, apart from the manufacturers' susceptibilities?

STOMACH LESIONS OF SYPHILITICS

Les Gastropathies des Syphilitiques. By Carlos Bonorino Udaondo. (Pp. 216; 19 figures. 32 fr.) Paris: Masson et Cie. 1936.

In this interesting monograph Professor Udaondo has brought together the literature on the subject of gastric lesions in syphilitics. Medical teaching in the matter has varied greatly over the years. In 1891 Chiari of Prague summarized the views of the time by asserting that lesions of the stomach may be provoked by syphilis, directly or indirectly. The direct lesions are rare, gummata and inflammatory infiltrations, usually in the submucosa; by fusion of gummata and the action of the gastric juice syphilitic ulcers may be formed, followed by scarring after healing occurs. The indirect lesions are due to alteration of the circulation following hepatic disease or to haemorrhages. The next step was to find the treponema in sections of the stomach obtained by operation or at necropsy. Technical difficulties have prevented much progress on these lines, and the therapeutic test of improvement under specific treatment which has been adopted clinically in diagnosis is under criticism. It is recognized, however, that lesions which are probably syphilitic may occur in the stomach—gummatous ulcers, a form of linitis plastica and hypertrophic gastritis—though there appears to be no consensus of opinion about the criteria necessary to establish the diagnosis. These lesions may occur in a patient with syphilis, and sections of the stomach wall must show gummata or syphilitic involvement of the submucous blood vessels.

Syphilitic lesions of the stomach have no characteristic which is an infallible guide in diagnosis. Gastric disturbances may also arise in patients with neurosyphilis. The therapeutic test is fallacious, though sometimes a most brilliant restoration clinically and radiologically may follow effective treatment.

DIAGNOSIS AND TREATMENT OF ORAL DISEASE

Oral Diagnosis and Treatment Planning. A Textbook for Students and Practitioners of Dentistry and Medicine. Edited by Samuel Charles Miller, D.D.S. (Pp. 620; 562 figures, including 15 colour plates. 30s.) London: J. and A. Churchill. 1937.

Under the editorship of Dr. S. C. Miller of the New York University College of Dentistry, twenty-two specialists have contributed the twenty-six chapters of which this book is composed. In a short preface the editor defends the multiplicity of contributors on the ground that "the magnitude of the subject made it impossible for any one mind to encompass it fully and properly"—a statement which might well make a student despair of ever mastering the intricacies of his profession; and, indeed, we cannot help thinking the book is over-specialized. However this may be, it contains a great deal of interesting matter. We note, as illustrative, a case of congenital diabetes showing extensive (pyorrhoeic) destruction of the alveolar bone in a child of 14 (p. 2); the daily progress of tongue cleaning in scarlet fever (p. 52); examples of cavernous sinus thrombosis following dental operations, one a case of "pulp-capping" (p. 200); a figure showing the solvent effects of fruit juice on the teeth (p. 263); and the description of "odontoclasia" as a special form of caries (p. 65).

With regard to the various subdivisions of the book, we note their comprehensive nature—for example, the chapter on diseases of the oral mucous membranes—and perhaps over-comprehensiveness, as in the list of habits that cause periodontal disease. The chapter on diagnosis for bridge work and bridge design is a thoughtful presentation of the possibilities of clean and aesthetic bridge work; that on the diagnosis of abnormalities of the temporo-mandibular articulation shows that the radiologist is obtaining considerable success in his attack on the difficult problem of making radiographs of that joint (we cannot see the "sloughing projection" in Fig. 10 (8)). The chapter on methods of laboratory diagnosis available to the dentist indicates how far dentistry has travelled since the days when it was a purely mechanical art; as Allen F. Newman says in his preface: "The dentist's responsibility, at present, is one of health service." We find the chapter on head pain hard to digest, and would like to see it presented in clearer form; and we wonder whether "cementoma" is the right word to apply to bone rarefaction on page 447, Fig. 7 (23).

IN PRAISE OF TEA

Opuscula Selecta Neerlandicorum de Arte Medica. Vol. XIV. Edited by M. A. Van Andel. (Pp. 465; illustrated.) Amstelodami Sumptibus Societatis. 1937.

The *Nederlandsch Tijdschrift voor Geneeskunde* was established to keep green the memory of little-known Dutch physicians who have deserved well of their country. This, the fourteenth volume of the *Opuscula Selecta*, like its fellows, is a monument of erudition and is well illustrated. Dr. Willem Piso is the first to be considered. He lived from 1611 to 1678, and went to Brazil as physician in the train of General Maurits of Nassau, who was appointed Governor of Brazil in 1636. Piso learnt the value of ipecacuanha in the treatment of diarrhoea and dysentery. No portrait of him has been traced hitherto, but Professor van Andel, who writes an introduction to his work, reproduces a miniature which he says, cautiously, he will not guarantee. The second article tells of Dr. Ten Rhyne (b. 1649). He published a valuable treatise on Asiatic leprosy, having gained an extensive knowledge of the disease whilst serving in Batavia. Dr. Schoute says in his

introductory notice that the remarks on the diagnosis of the disease and on the symptoms of its earliest stages are especially valuable.

The last three hundred pages of the volume consist of a reprint of the *Treatise about the most excellent herb Tea* by Dr. Cornelis Bontekoe (1647–85), which was printed at The Hague in the year 1678. The whole treatise is excellent reading. Dr. Bontekoe approaches his subject with a diatribe on contemporary doctors and an essay on good living, via Predestination to Life. Having thus proved himself to be a master of vituperation and a sound Calvinist, he proceeds to consider the effects of "tea water" on the different organs of the body and its value on the social customs of the Dutch in general. It is amusing though it is written in all soberness, and would have gladdened the heart of Dr. Johnson, for he says: "I have no scruple in advising [people] to drink fifty or a hundred or two hundred cups at a time. I have often drunk as many in a fore- or afternoon, and many people with me, of whom not a single one has died yet. But I do not think that anyone need imitate this. I only alledge it to show there is no harm in tea, so there is no reason to be afraid of drinking ten or twenty cups; it is not like wine or beer, which go to the head as the saying is." Dr. de Feyfer, who writes an introduction, points out that Bontekoe was hated very heartily by his contemporaries, who attributed his enthusiasm for tea to money supplied by the East India Company in return for propaganda which filled their coffers.

The volume as usual is printed in Dutch with an English translation on each opposite page. The English is idiomatic, and except in a few minor instances is accurate.

PHYSICAL PHILOSOPHY AND BIOLOGICAL PROBLEMS

Biology and the New Physics. A Plea for a Consistent Philosophy of Life. By C. J. Bond, C.M.G., F.R.C.S., F.L.S. (Cloth 2s. 6d. net; paper cover 1s. 6d. net.) London: H. K. Lewis and Co., Ltd. 1936.

There is no dearth of books explaining the modern conceptions of physics, but most of them are written by physicists and astronomers, and though the authors occasionally deal with biological problems, these excursions into unfamiliar territory are seldom happy, since they usually result in special prominence being given to highly doubtful experimental results. Biologists, on the other hand, have shown themselves averse to considering the implications of the recent advances in physics. This aversion has a simple historical explanation, because the whole advance of the biological sciences during the past century depended on the abandonment of the old vague vitalistic ideas and the interpretation of the obscure phenomena presented by living matter by means of the known laws of chemistry and physics. This method has yielded wonderful results, and biologists naturally cherish the belief that the same method if pressed far enough will solve the ultimate problems of the nature of life and evolution. They naturally find it disconcerting to be informed by physicists that the fundamental laws on which the whole structure of biological science has been based merely express statistical probabilities, and give little information regarding individual behaviour. Those subjects which have the smallest quantity of accurate data cherish their scanty possessions the most jealously, and it would seem possible that in the future the biological sciences may form the last home of pure determinism. For these reasons it is interesting to read an estimate of the effect of the changes in physical philosophy on the fundamental problems of biology written by one whose life experience has been concerned with biological material. Such a survey has been provided in the short volume entitled *Biology and the New Physics*, which contains an account of the presidential lecture delivered by Mr. C. J. Bond at the centenary meeting of the Leicester Literary and Philosophical Society. The range covered by the author is most simply indicated by his chapter headings: The atomic world, the inconceivably small; the astronomic sphere, the inconceivably vast; life and mind; the method of evolution; the existence of evil.

The author gives in less than 70 pages a bird's-eye survey of the salient features of a vast territory, and finally considers what help such a survey provides for the framing of a consistent philosophy of life. The consideration of this range of knowledge in this space may seem to some an unwarrantable audacity, but it must be remembered that most of the fundamental problems of life can be presented in a sentence and answered in a word, and the fact that mankind has quarrelled for thousands of years as to when the word should be yes and when no does not affect the simplicity of the problem that must finally be faced in each case. The general line of thought followed by the author is indicated by the following sentence:

> "This capacity for organization or arrangement of units which is associated with an entity or organism when functioning as a whole seems to depend on a basis of indeterminacy and, as we have already seen, from embryological, ontological, and other evidence, the organizing process itself seems to employ the experimental method."

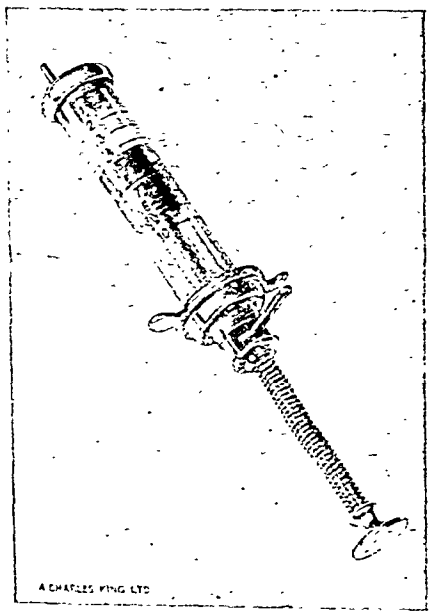
Notes on Books

For its second edition the textbook on *The Diseases of Infants and Childhood*, by Professor J. P. CROZER GRIFFITH and Professor A. GRAEME MITCHELL, has not only been entirely revised and reset, but it is now issued in one volume instead of two. This has called for a certain amount of rearrangement. Material which may not be needed by the student in his daily work has been put into small type. References are now included at the end of each chapter, and these bibliographical summaries are a valuable part of the book. As with the first edition, this new version can be thoroughly recommended as a first-rate textbook on the subject of paediatrics. It is published by W. B. Saunders Co. at 42s.

The Lung, by WILLIAM SNOW MILLER (Baillière, Tindall and Cox, 34s.), would deserve high praise for the illustrations alone, of which many are original, and no fewer than twenty are coloured. But in addition the author writes with the experience behind him of forty-seven years' study of lung structure. This no doubt also accounts for a conciseness of style that has enabled an enormous amount of information to be included in comparatively little text without danger of straining the reader's attention. But let it be said at once, the book is mainly for the anatomy specialist. The clinician will miss that association of structure with function and disease which enables him to apply the information gained from the basic medical sciences to his daily work. The first chapter describes the gross anatomy of the lungs. The second and third, on the trachea and bronchi and on the intrapulmonary bronchi and bronchioli, contain the author's interesting reconstructions of carinal cartilages, the trachealis muscle, and of bronchial muscle. The fourth chapter describes in detail the air spaces, and gives the author's original models showing the existence of atria. The next four are devoted to the blood vessels, the lymphatics, the lymphoid tissue, and the nerves respectively. In another chapter is discussed the pleura, followed by a unique discussion of the architecture of the lung in terms

of key points—points where certain structures are constantly found. Finally Dr. Miller, in a historical sketch, traces the views that have been held by various authors on the arrangement of the air spaces from the seventeenth century to the present day.

Some readers may be glad to know of a clearly written little book *Business Affairs and Book-Keeping* by WINIFRED E. GILL, B.Sc. (Longmans, Green and Co.; 3s. 6d.). Part I, on business affairs, deals in turn with money and banking, law of master and servant, insurance, rates and taxes, law of landlord and tenant, and office management. Part II gives practical instruction in book-keeping, with special reference to household management.

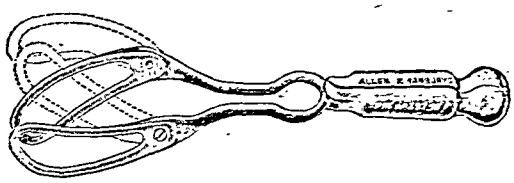


Medical Harrovians will like to hear of the appearance of a fifth edition of the *Harrow School Register* (Longmans, Green and Co.). This covers a period of ninety years of admissions to the school and is divided into two volumes, one for 1845–1898, the other for 1899–1937. The editor is Mr. John H. Stogdon, and the head master contributes a preface. The price of each volume is 15s. 6d.

Preparations and Appliances

NEW SYRINGE FOR INTRAVENOUS INJECTION

Dr. MASSEY DAWKINS (London, N.W.3) writes:

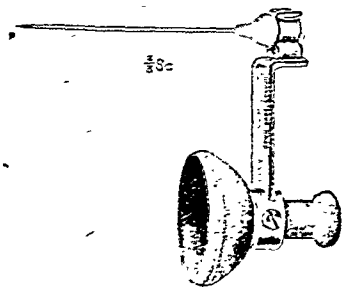


I have found the syringe shown in the accompanying figure invaluable for giving intravenous anaesthetics, or indeed for any intravenous injection. It is a modification of the ordinary 10 c.cm. Record syringe, but the piston rod has been extended and fitted with a spring. The spring tends to withdraw the

piston, but can be fixed in any given position by means of an annular catch, which can be put out of action by depressing it with the thumb. In practice the catch is depressed and the piston automatically withdraws the anaesthetic solution from the ampoule. When the amount to be injected has been decided the catch is set for that amount. The needle is then pushed into the arm and the catch released; it will then be found that the piston will not suck back until the vein is entered, since, if the needle is outside the vein, the surrounding tissue is sucked against the bevel of the needle and the piston remains stationary. Thus it is almost impossible to give a perivenous injection. A further advantage of this syringe is that the whole procedure can be effected with one hand. This instrument has been made for me by Messrs. A. Charles King Limited, 34, Devonshire Street, W.1.

REVERSIBLE PELVIC CURVE FORCEPS

Dr. DAVID PRICE (Somerset) writes: Delay in the second stage of labour, with consequent maternal exhaustion, can be terminated safely by the use of reversible pelvic curve forceps, which enable one to rotate the foetal head without damage to maternal tissues and extract it without removal of the



blades (a process necessary in the existing rigid types of midwifery forceps, and involving much manipulation and often return of the foetal head to its occipito-posterior position). When there is delay in the second stage and a large caput it is not easy to diagnose the position of the occiput. I apply the forceps and make traction; if that "no advance" feeling ensues, I press upwards and try rotation in the easiest direction. If no rotation is easily obtained a manual examination is made, but it is surprising how often easy rotation is accomplished. The handles then swing on their hinges well forward, and extraction is accomplished by one steady pull. The degree of tension of the hinges can be controlled by a turn-screw. I find that if one can reverse the curve by a sharp jerk the tension is about the best for application. Experience of the use of this instrument has proved other advantages: (1) application of the second blade in any maternal position is easy; (2) the blades find the easiest route into position for locking without force; (3) there is a minimum of pressure signs upon the scalp and face even after a difficult extraction. The instrument is made for me by Messrs. Allen and Hanburys Ltd. of London, E.2.

NEEDLE HOLDER FOR THORACOCENTESIS

Dr. M. W. LLOYD OWEN, M.B. (London, W.2), writes:

In aspirating fluid from the chest it is often found that the needle will not stay in the position inserted at right angles

to the chest wall. When the aspiration is being performed with a two-way syringe the needle has to be held in position by an assistant. The necessity for an assistant can be overcome by the use of a simple but effective sucker apparatus with a metal needle attachment which keeps the needle in the desired position. It sometimes happens that the sucker part of the apparatus will not adhere properly in those patients with rather prominent ribs, but this difficulty can be overcome by moistening the sucker a little before applying it to the chest wall. The instrument has been made for me by Messrs. Down Bros. of London, from whom it can be obtained.

SOME PROBLEMS OF THORACOPLASTY

The principles underlying the treatment of pulmonary tuberculosis by thoracoplasty have within recent months been the subject of comment in these columns.[1] In his admirable survey before the Tuberculosis Association Mr. George Mason stressed[2] a difficulty which arises with this operation—namely, that of keeping the "filleted" chest wall adequately immobilized. In view of this and the enormous rise in operative mortality among patients who do not fulfil the high standards of the ideal indication, the following conclusion of Mr. Mason's should be treated with caution: "The limitation of our activities to favourable cases, although good for our statistics, would be a cowardly desertion of those numerous cases for whom the operation offers the only prospect of recovery." At all events, the advice contained in it should be followed only by surgeons with much experience of thoracoplasty, and only after careful consultation with a tuberculosis physician who has had the patient under observation for a long time.

The patient to whom thoracoplasty is suggested has the right to ask three questions which the medical attendant must be prepared to answer. (1) How long am I likely to live if I do not submit to the operation? (2) What is the risk of my dying from the operation? (3) If I get over the operation what are my chances of being completely cured? Reliable statistics have been published from abroad giving the average length of life of the patient with chronic pulmonary tuberculosis with cavitation for which thoracoplasty is recommended. It is, however, only an "average," and many factors determine the length of life, such as the patient's general and psychological condition and his economic and social environment. The patient himself is apt to accept the more optimistic of the two extremes on which the average is based, and the answers to the last two questions must therefore compare favourably with this optimistic assumption. It is not enough to give an operative mortality of "only" 15 per cent. and a cure of 10 to 20 per cent. on the ground that the outlook is "otherwise hopeless." The figure of operative mortality varies greatly in different statistics. Among the most favourable is that of Archibald in 1927—about 4 per cent. in "favourable" and "doubtful" cases. In the recently published analysis of all the thoracoplasties done at the Brompton Hospital since 1922[3] the operative deaths amount to 14.6 per cent. This figure is on the high side, but it would be unfair to make comparisons with the figures of other workers, owing to the difficulty of obtaining a standard for the term "operative mortality," apparently used by some surgeons with much elasticity. Another result of importance is the percentage of "practical cures," "returned to work," or "living and well" in the survivors. Sellors in 1933 collected 3,500 cases from various sources: 45 per cent. of these had returned to work. In 1927 Archibald had "practical cures" in 66 per cent. of "favourable" cases and 38 per cent. in "doubtful" cases. Gravesen in 1930 claimed 42 per cent. cures. Sauerbruch in 1935 stated[4] that until recent years the number of permanent cures in his clinics amounted to 70 to 80 per cent.: "the average case operated on being of a poorer type, this percentage is not now so high; it is still, however, 40.6 per cent." Of the 437 patients operated on at the Brompton Hospital between 1922 and 1935 only 14.9 per cent. are in the category "living and well." The term implies that "he or she is living and has lived for at least one year the ordinary life of his or her particular class, and if this involves working, as in the vast majority of cases it does, that he or she is working full time; and, secondly, that there are no symptoms whatever attributable to pulmonary tuberculosis." Is this great difference to be attributed merely to dissimilarity in definition? No doubt the staff at Brompton will soon elucidate this problem, and a fuller report will be of great interest.

In the meantime it is permissible to speculate on the factors that determine the number of cures. As none but highly skilled surgeons would attempt the operation, technical operative skill can be a factor of only minor importance. Four other factors must, however, be considered, each of which might influence either or both the operative mortality and the percentage of cures. In the selection of patients the general condition will undoubtedly affect the former, but an ultimate cure is more likely to be determined by the type of lesion in the lung. Considerations of the fitness of the patient for an operation have perhaps tended to obscure

the importance of detailed investigation of the cavity to be collapsed, and existing methods—tomography, kymography, and bronchography—have not been made full use of. It is possible to overlook the fact that some cavities will not close completely whatever the type of thoracoplasty performed. Perhaps this would be better realized if there were more opportunity of examining the lungs of people dying of pulmonary tuberculosis. There can be no question that the type of operation is intimately related to the end-results, as recent discussions have shown. But these discussions have unfortunately also produced no consensus of opinion.

Whereas some surgeons would favour the partial operation whenever possible, others maintain that the complete operation is more likely to prevent relapse. Though some now insist that complete collapse of the upper lobe can often be obtained only if the rib resection is associated with an extrafascial apicolysis, others argue that the paravertebral operation properly carried out does all that is needed. But apart from this it should be stressed that the aim of a thoracoplasty should be to render the sputum negative, as determined by culture and, if necessary, by examination of the gastric contents. If that result is not obtained further operative procedures must be considered, even at the risk of increasing the total operative mortality. It is probable that these supplementary operations are often done in Sauerbruch's clinics and may account for his high proportion of cures. Finally, the social and economic status of the patients in any series must be taken into consideration in comparing results, since "after-care" plays an important part. This factor alone would favour greatly Gravesen's figures as compared with those at the Brompton Hospital. Thoracoplasty is a confession of therapeutic failure. Indeed this is true of much of the surgery of chronic conditions. But in view of the present state of tuberculosis control the usefulness of the operation has not yet reached its peak.

WORLD-WIDE PREVALENCE OF ACUTE POLIOMYELITIS

Simultaneous reports of a high incidence of poliomyelitis in several countries far apart may well cause health authorities in this country to wonder when our customary sporadic cases in autumn each year are to become a major epidemic. In recent weeks in Melbourne alone 185 cases have been reported, with thirteen deaths, of which four were in adults. The Australian outbreak appeared first in Victoria, and steps were taken to prevent the entry of children without a medical certificate of twenty-one days' isolation into New South Wales by means of a police patrol along the border, but despite every measure the disease has secured a firm hold in Melbourne and shows no sign of abating. The epidemic now raging in Chicago appears to have originated in the return to the city of school children from summer camps, where the disease had been prevalent for some time. The chief administrative action taken by the Board of Health has been to postpone the reopening of the public schools and parish schools until the outbreak has terminated, or, at least, until the number of fresh cases has appreciably diminished. In August a total of 109 cases were reported, which is ten higher than that of the record month in the 1916-17 epidemic. Almost simultaneously Ontario has been experiencing the worst epidemic of poliomyelitis in its history; so far the number of cases reported has reached 700, of which the majority are in Toronto. Here, too, the chief single measure adopted by the health authorities has been to defer the reopening of the schools after the summer holidays. The only European country to suffer from a severe visitation of poliomyelitis in recent years has been Denmark, particularly in 1934. At present there is a considerable prevalence of the disease both in Copenhagen and in country districts, but, on immunological grounds, it is unlikely that a large epidemic will follow.

Some lessons in poliomyelitis control may be learned from the experience of Manitoba, which has been fully described in a report[1] on the epidemic in 1936 in that Province. While it proved to be the largest epidemic in its history with a case rate of 75.7 per 100,000 of the population, it was relatively mild in comparison with the Danish epidemic of 1934, with a rate of 124.9 per 100,000. It is noteworthy that the incidence in Manitoba was twice as high in the rural areas as in certain urban districts (notably Winnipeg, which is the largest urban centre); the explanation is probably to be found in the fact that Winnipeg experienced an outbreak of considerable size in 1928, at a time when the rural areas mostly escaped. While the highest incidence fell on the 5-10 years age group, the case fatality was greatest at ages 15 to 19 years. In all, there were 539 cases with a case fatality of 6.1 per cent. In 57 homes (12 per cent.) more than one case occurred in the family, accounting for nearly 25 per cent. of the total. In agreement with general experience, an increasing proportion of cases were diagnosed in the pre-paralytic stage as the epidemic progressed, due to the fact that both

[1] *Can. publ. Hlth. J.*, 1937, 27, 363.

the general public and the medical profession became "poliomyelitis-conscious," while the case fatality fell steeply. It is only natural to ascribe this lowering of fatality to immune serum whenever it is administered, but it is common knowledge that a like fall frequently occurs whether serum is given or withheld. The conclusion that the favourable results described are due to intramuscular inoculation of 20 c.cm. of immune poliomyelitis serum must be accepted with considerable reserve, particularly in view of the fact that a positive diagnosis of poliomyelitis was frequently made on the finding of headache, fever, gastric upset, irritability, and stiffness of the neck or back, without investigation of the cerebrospinal fluid. Indeed, the findings in the cerebrospinal fluid were often observed to be equivocal; of 170 fluids examined, 22 per cent. had less than ten cells per c.cm. Immune serum does not appear to have been employed in passive immunization of contacts, probably because of lack of supplies; nasal sprays of picric acid solution, such as have been previously described in these columns,[2] appear to have been widely employed, but the authors of the Manitoba report give no details of cases and make no comment on its efficacy. On the whole, the authorities concerned were satisfied that the prophylactic and curative measures they employed were effective in checking the disease or, at least, in averting its worst consequences.

BOECK'S SARCOID

Because of some histological resemblance to sarcoma, Boeck in 1899 designated as multiple benign sarcoid of the skin the condition which Besnier had described as lupus pernio. In addition to the skin lesion these earlier workers noted that lymph nodes, mucous membranes, bones, and internal organs might be involved, and on the basis of this recognition, as also on the supposition that the lesion was tuberculous in origin, Boeck suggested later the name "benign miliar-lupoid." While the dermatologists were concentrating on their special aspects of this problem, radiologists were reporting unusual changes in the bones of the hands and feet, which Kreibech in 1904 definitely associated with lupus pernio. It was, however, not till 1920, when Jüngling gave a detailed description of these bone changes, that their nature was clearly appreciated; and eight years later this observer recognized that the condition he had described as ostitis tuberculosa multiplex cystica had indeed a close association with the cutaneous and glandular affection known as Boeck's sarcoid and lupus pernio. In the meantime Schaumann had made extensive studies of the glandular part of these associated lesions. He concluded that the affection was a generalized lesion of the reticulo-endothelial system, and because of its superficial resemblance to Hodgkin's disease he named it benign lymphogranulomatosis, believing that the affection ran a mild course and, further, holding that it was tuberculous in origin. From the voluminous literature on the subject (Kissmeyer in 1932 reviewed 200 cases) it appears that the affection is one that starts in early adult life. The progress is insidious; finally the disease produces obvious changes, most often in the skin, in the lymph nodes, in the bones of the hands and feet, or in the lungs. In a few instances the earliest pronounced symptoms were referable to the lungs. The mucous membrane of the nose, the nasopharynx, the larynx, and the conjunctiva may be involved, and the tonsils are not infrequently affected. Ocular complications in the form of bilateral iridocyclitis are being reported with increasing frequency. The unity of these diffuse manifestations lies in the characteristic histological appearance of large, palely staining epithelioid cells arranged in the form of miliary tubercles, sometimes lying as isolated structures in a comparatively normal tissue and sometimes occurring in groups or strands. These collections of cells may become so large as to replace most of the normal tissue. They are not outlined by an inflammatory zone of lymphoid cells; in fact, the absence of inflammatory reaction in the surrounding tissue is a characteristic feature. Although mild necrosis of some central cells may be present, caseation is always absent and healing may occur through fibrosis. Longscope and Pierson,[1] in an excellent survey of the subject, report eight cases of their own, and suggest that uveo-parotid fever, with its involvement of lymph nodes and uveitis, should be regarded as yet another manifestation of Boeck's sarcoid. In one of their cases with involvement of the lung there were bilateral iridocyclitis and swelling of the parotid gland; histological sections of a lymph node and of the parotid showed lesions of the type of Boeck's sarcoid. They quote two other cases recently recorded by W. J. B. Slot which have a similar association. In a study on the clinical and histological similarity of Boeck's sarcoid and uveo-parotid fever T. K. With[2] urges the same unifying conception. Additional evidence on the same lines comes from a newly reported case of uveo-parotid fever by W. C. Thompson.[3] In all these discussions the question of tuberculosis looms large. Schaumann,[4] who has studied deeply the general aspect of the affection, believes, as already noted, that it is a mild tuberculosis. On the other hand, dermatologists have been impressed by the similarity of the bone changes to those seen in leprosy, and Jordon and Osborne[5] uphold the dual aetiology, both tuberculosis and leprosy, in a full account of the affection given from the dermatological aspect. Longscope and Pierson cautiously conclude that the aetiology is undetermined; they are not impressed by the evidence brought forward in favour of tuberculosis. Boeck's sarcoid is, of course, not the only dermatological condition that of late years has been shown to have general implications. The conception of tuberosclerosis with its widespread cerebral involvement

arose out of Pringle's adenoma sebaceum, and what appears to be another association is reported by Albright, Butler, Hampton, and Smith[6] in a recent issue of the *New England Journal of Medicine*. They describe five cases of their own and draw on ill-defined cases from the literature to illustrate what they consider a new syndrome characterized by: (1) areas of pigmentation on the skin; (2) multiple bone cysts, frequently localized to one bone, having the features of osteitis fibrosa; (3) precocious puberty in females, but apparently not in males. This association of skin and bone lesions has some superficial resemblance to the associations of Boeck's sarcoid, but their histology and course appear to be wholly different.

ALCOHOL AND MOTOR ACCIDENTS

Estimations of blood alcohol have been used for several years in Sweden as a legal test of alcoholism in motorists involved in accidents. The method has been adopted in Germany, and Dr. K. Hoffmann has published a review of the results obtained during the past four years.[1] His report deals with several thousand tests of blood taken from motor-car drivers. The results of clinical and chemical examinations of about 2,500 cases are set out in a table. The clinical examination divided the cases into three groups: (i) sober—that is, unaffected by alcohol (36 per cent.); (ii) slightly affected (45 per cent.); and (iii) definitely intoxicated (hochgradig Alkoholbeeinflussung) (18 per cent.). Results of blood tests can be divided into three groups of comparable sizes: (i) less than 1 mg. alcohol per c.cm. blood (34 per cent.); (ii) 1 to 2 mg. per c.cm. (56 per cent.); and (iii) more than 2 mg. per c.cm. (10 per cent.). It is usually stated that a concentration of alcohol in the blood of 1 mg. per c.cm. produces symptoms of intoxication in about half the population. This concentration is equivalent to a total body content of alcohol of about 50 grammes in a person weighing 70 kilogrammes, and this amount of alcohol is contained in about three "large whiskies" or 3 to 4 pints of beer. The figures under discussion show that half the persons with a blood alcohol content of 0.6 to 0.8 mg. per c.cm. were slightly under the influence of alcohol, while half those with a blood alcohol content of 2.2 mg. per c.cm. were definitely intoxicated. These results suggest that the class "slightly under the influence of alcohol" must include a wide range of conditions. The clinical and chemical tests are in fair agreement. For example, out of 750 persons with less than 1 mg. of alcohol per c.cm. of blood only ten were found to be definitely intoxicated, whereas out of 250 persons with more than 2 mg. per c.cm. 130 were classed as definitely intoxicated and only nineteen as sober. Individuals, however, showed striking variations—for example, three persons with less than 0.4 mg. alcohol per c.cm. blood were found to be definitely intoxicated, while five individuals with more than 2.4 mg. per c.cm. showed no signs of alcoholism. Individual variation as regards susceptibility to alcohol is notorious, and the blood analyses confirm this familiar fact, since they indicate that some individuals are more affected by an amount of alcohol corresponding to one "large whisky" than others are by six times this quantity. In the past it has been suggested that tolerance to alcohol is due chiefly to delayed absorption, but these results imply a definite tolerance of the brain to alcohol in the blood. The results therefore show that the alcohol content of the blood does not with any certainty indicate the degree of intoxication. On the other hand, it does provide a fairly accurate estimate of the amount of alcohol that the subject has drunk recently. The medical profession is only too well aware of the unsatisfactory results of the estimation of alcoholism by clinical examination. The contradictory medical evidence so often given in law courts proves this. The estimations of blood alcohol at least provide objective data which indicate strong probabilities. If a man has a blood alcohol content lower than 1 mg. per c.cm. he is very unlikely to be intoxicated, and if he has more than 2 mg. per c.cm. it is very unlikely that he is in a fit state to drive a car. The compulsory taking of blood samples is apparently contrary to English common law, but it would be a considerable advance if blood samples given voluntarily could be tested officially. The amount of blood needed for the test is only a few drops, and since the rate of metabolism of alcohol in the body is fairly constant, the alcohol concentration in the blood at the time of an accident can be estimated with fair accuracy from a sample taken some hours later. Objective evidence of this type would certainly assist in those difficult and unfortunate cases where Dr. A. states that the accused was intoxicated and Dr. B., who examined the accused an hour later than Dr. A., states that he was perfectly sober.

PNEUMONIA TO-DAY

Dr. Campbell Howard is justified in devoting a monograph to the diagnosis and treatment of pneumonia,[1] not only because, as Osler said, it has replaced consumption as the "Captain of the Men of Death," but because its study involves the principles of all medical diagnosis and treatment. In this respect it has replaced typhoid fever, now a comparatively rare disease, in lectures on systematic medicine. The modern history of pneumonia dates from the discovery of the pneumococcus in 1884, which was followed by the theory of a primary septicaemia, and then by the recognition of types in 1910. It is perhaps unfortunate that the number of types has now reached twenty-nine, according to some observers, for this to a large extent deprives typing of the clinical value it possessed so long as the classification into four main types held the field. As to the primary septicaemic nature of pneumonia, Dr. Howard appears to be doubtful regarding the demonstrable presence of the cocci in the blood stream as an indication of the severity of the disease (which it undoubtedly is) and as a secondary event (which is more

[1] *The Diagnosis and Treatment of Pneumonia*. Reprinted from Oxford Monographs on Diagnosis and Treatment. By Campbell P. Howard, M.D., C.M., F.R.C.P. & S.Can. H. Milford, Oxford University Press. 31s. 6d.

controversial). He quotes the evidence of bronchoscopy, which in fifteen cases revealed the presence of an atelectasis, apparently secondary to a bronchitis, and of *x* rays, which may show a displacement of the mediastinum and diaphragm towards the affected side in the early stages of the disease. This view would seem to upset the classical distinction between lobar-pneumonia and bronchopneumonia, which the German school was once so unwilling to accept. That atelectasis occurs in the early stages of influenzal pneumonia of the epidemic type is undoubtedly true—but this is generally regarded as a confluent bronchopneumonia. Dr. Christian, in his introduction to the monograph, attributes the therapeutic nihilism of the recent past to the predominating influence of morbid anatomy, the post-mortem examination revealing a condition apparently impossible to treat successfully. That was the consequence of studying end-results, but even to-day there is too much loose and contemptuous talk about "the bottle of medicine," which ignores the fact that as the body is continuously regulating itself by chemical means there is nothing intrinsically absurd in an attempt to modify its reactions by drugs. Dr. Howard therefore does not disdain to devote a section to special methods in the treatment of pneumonia. Among the non-specific methods he speaks cautiously concerning optochin, but does not mention transpulmin, another quinine derivative which seems specially useful in old or debilitated subjects. There is a full review of specific measures, which comes to a rather more optimistic conclusion as to the benefits of Felton's serum than is generally held in this country. The author is very doubtful as to any therapeutic value of vaccines in pneumonia, apart possibly for prophylaxis.

THE LEAGUE OF NATIONS AND NARCOTIC DRUGS

The serious situation in the Far East by reason of the increasing production of, and illicit traffic in, narcotic drugs has recently been reviewed by the Opium Advisory Committee of the League of Nations. China claims to be pursuing a six-years' plan for restriction of poppy cultivation, which was launched in 1934, and in two provinces, eight districts, and three municipalities the use and sale of opium are absolutely prohibited. There are, however, still 3,700,000 registered smokers in China and 300,000 addicts were under treatment in 1935. In the provinces now subject to Japanese influence the systematic increase of poppy cultivation and of the sale of opium is stated for the past year to have "attained alarming proportions." Illicit traffic in opium, morphine, and heroin is rapidly increasing in Manchuria and Jehol and is encouraged as a fruitful source of revenue. It was estimated that 500 kilograms of heroin were exported each week from Tientsin and that 90 per cent. thereof went to the United States. Canada also is suffering from this flow of narcotics from the Far East to the Pacific coast, and there has been no improvement during the last twelve months. The Advisory Committee recorded its alarm at the situation in the Chinese provinces under Japanese jurisdiction as constituting a real danger to the whole world. As regards the legitimate manufacture of morphine, heroin, and cocaine it would appear, from the statistical returns made by the Governments parties to the conventions of 1925 and 1931, that the annual production of these alkaloids now approximates closely to the level of legitimate world requirements as accepted by the League. It is somewhat disquieting to learn that poppy straw from the dried plant is being increasingly utilized as raw material for the manufacture of morphine. The Advisory Committee has been moved by a resolution of the International Labour Conference to tighten up the control of opium used for smoking in territories where the sale of "prepared" opium is still authorized, with a view to suppress smoking of opium among workers. There appears to be indisposition to proceed with the convening of an international conference on limitation of production of raw opium, as contemplated by the Council and the Assembly of the League of Nations. While the Governments concerned have stated that they are "prepared to agree to far-reaching measures for the final suppression of opium-smoking" the Advisory Committee is anxious for further consideration and revision of the information already at its disposal before embarking on a conference "whose reference should be sufficiently wide to include any problem relating to the production and use of opium."

MAGNESIUM SULPHATE TREATMENT OF ECLAMPSIA

The administration of magnesium sulphate by subcutaneous injection has of recent years been fairly widely used to control the fits in eclampsia. Professor W. Stroganoff and Dr. O. Davidovitch[1] have collected from the American and European literature reports on 449 cases so treated with a mortality of 9.1 per cent. Recent Russian medical literature mentions 245 such cases in which there was a mortality of 3.3 per cent. These results produced a favourable impression on Stroganoff, who now reports 200 cases treated on the lines which he has previously described—using morphine and chloroform, with venesection and artificial rupture of the membranes—with the substitution of magnesium sulphate for chloral hydrate. The magnesium sulphate was injected subcutaneously thirty minutes after the first injection of morphine. The average dose was 6 grammes, preferably in the form of 40 grammes of a 15 per cent. solution, followed by a further similar injection in five hours if there had been another fit. The dosage was diminished or the injections discontinued if the fits ceased. If the fits went on, the patient received further doses, the maximum advisable being a total of 24 grammes in twenty-four hours. It was found that smaller doses often failed to control the convulsions. One patient who died following rupture of the lower segment of the uterus, after having had sixteen fits, had been given only 2.6 grammes. In the 200 cases which Stroganoff records there were six deaths, a mortality of 3 per cent. The average duration of stay in hospital was 13.7 days. Sixty-nine of these patients had normal deliveries, artificial rupture of the membranes was necessary in seventy-three cases, forceps delivery in fifty-four

[1] *J. Obstet. Gynaec. Brit. Emp.*, 1937, 44, 289.

cases, and there were fifty-six venesections. Stroganoff finds magnesium sulphate a powerful means of combating eclampsia and hopes that he will succeed eventually in reducing the mortality from eclampsia to below 0.5 per cent. for early cases in which severe complications are absent, and to a figure between 2.5 and 4 per cent. for all cases. He does not commit himself as to whether magnesium sulphate or chloral hydrate is the more efficient in treating eclampsia. He does state, however, that the former has the more certain effect in stopping fits, although he admits that while the magnesium sulphate was given thirty minutes after the first injection of morphine, chloral hydrate was not administered until an hour after the morphine. In certain rare cases the injection of magnesium sulphate was found to cause alarming symptoms, such as acute cyanosis, dyspnoea, and a feeble pulse. Should this happen it is advised that 10 grammes of a 5 per cent. solution of calcium chloride be given intravenously. Other complications included the formation of abscesses at the site of injection; for this reason the injections were subcutaneous rather than intramuscular. One further striking finding was that whereas the total mortality among the 200 cases was only 3 per cent., in the ten cases of multiple pregnancy the mortality was 40 per cent. Stroganoff appeals for further investigations into the treatment of eclampsia by magnesium sulphate, both with chloroform and morphine, and with ether but no morphine.

GIGANTISM

Gigantism is a rare condition of interest not only to the visitor to circuses but also to the medical man. A recent addition to the literature on this subject is supplied by Dr. H. Gray,[1] who has reported a case under the title of "The Minneapolis Giant." The patient's paternal grandfather, the Norwegian giant, was reputed to be 8 ft. 4 in. in height, while his father's height was variously stated by the patient to be 7 ft. 6 in. and 6 ft. 4 in. and his mother's 6 ft. 2 in. The patient himself was aged 46, was obviously acromegalic, measured 7 ft. in height, and weighed 19 stone; at the age of eight he was 6 ft. in height. A year later he started travelling in shows all over the world, and appeared in carnivals, circuses, and "so many movies that he cannot remember the names of any, except Harold Lloyd's *Why Worry?* in 1923, when he was advertised as being the second tallest man in the world," a claim which the author points out would seem to indicate insufficient information about other living giants. His habits were irregular, and although he seldom drank alcohol, on one occasion he was arrested by eight policemen because he acted a little peculiarly, having consumed by his account "maybe five or six cases of whisky." In jail his breakfast consisted of two gallons of coffee, of which beverage he was inordinately fond. His muscular strength was never remarkable, his memory was poor, he had had bitemporal hemianopia for the last fifteen years, and for five years epileptic convulsions and uncinate fits. He only noticed the enlargement of his hands and feet at the age of 31, five years after his acromegaly was recognized at the Mayo Clinic—this extraordinary delay in a patient's appreciation of the enlargement of his extremities was also observed by Dr. Leonard Mark in his book on his own case. The hair of the Minneapolis giant was of feminine distribution, and he seldom needed to shave; his penis was infantile, and his testes small and soft. The pituitary fossa was large, but there was no evidence of erosion of the bone. The basal metabolic rate was minus 17 per cent. His condition was considered to be due to a tumour of the eosinophil cells of the anterior lobe of the pituitary. Early in life this had been manifested by simple gigantism with destruction or inhibition of the gonad-stimulating cells and consequent failure of sexual development and lack of hair. After a period of more or less arrest the tumour evidently began to grow again, causing acromegaly and pressure on the chiasma with optic atrophy and bitemporal hemianopia. Among taller giants than the one referred to here may be mentioned the Gallatin giant (8 ft. 6 in.) reported by Lackey in 1899, the Irish giant (8 ft. 6 in.) reported by Cunningham in 1891, the Alton giant Wadlow (8 ft. 5 in.) reported by Barr in 1936, Ranke's giantess Wehde (8 ft. 4½ in.) and the Austrian giant (8 ft. 4½ in.) reported by Topinard in 1885. Gigantism has been described as acromegaly during the period of growth, and can only occur before the epiphyses have united. Because of the presence of a large and extremely vascular thymus in cases of acromegaly, some of the earlier observers regarded this condition as primarily due to excessive activity of the thymus, the enlargement of the pituitary being considered a secondary change. It is generally accepted now, however, that the anterior lobe of the pituitary is the growth regulator of the whole body, and that both gigantism and acromegaly are due to hypersecretion of the eosinophil cells of the anterior lobe, which may either contain an eosinophil adenoma or show hyperplasia of the eosinophil cells without any pituitary enlargement. Experimental evidence of the growth-promoting power of the anterior pituitary was obtained by Evans and Long, who first prepared extracts of the gland capable of producing gigantism in young rats.

[1] *Ann. intern. Med.*, 1937, 10, 1669.

Major-General William P. MacArthur will succeed Lieut.-General Sir James Hartigan as Director-General of Army Medical Services when the latter completes his tenure of office on March 1, 1938.

The Prime Minister will inaugurate the national campaign to encourage the wider use of the health services at a reception given by the London School of Hygiene and Tropical Medicine on the evening of Thursday, September 30. His address will be broadcast on the National wave-length at 9.30.

We have to announce with great regret the death in Chicago on September 2 of Dr. George H. Simmons, Editor Emeritus of the *Journal of the American Medical Association*. An obituary notice, with portrait, will appear in our next issue.

ANAESTHESIA IN GENERAL PRACTICE

This is one of a series of articles, contributed by invitation

ANALGESIA IN MIDWIFERY

BY

R. J. MINNITT, M.D., D.A.

The time has passed when the obstetric practitioner can satisfy the requirements of women in labour simply by committing their mental and physical sufferings to the care and moral support of a good nurse. The public is becoming increasingly aware that much can be done for the relief of pain, and an article on recent methods employed for the purpose is therefore justified. Two main types of administration are available: (1) drugs given by the oral route or hypodermically, and (2) inhalational analgesia.

Drugs

"Twilight sleep" is the term applied to a morphine-scopolamine narcosis in which an amnesic state is produced. It must be clearly understood that the labour is not painless, but when the narcosis is successful the patient should have no recollection of labour. The objection to its use in general practice is that constant supervision is necessary. There may be increased danger to mother and child unless the dosage has been very carefully gauged. This is controlled by strict observation of the patient, the technique being as follows.

When the pains are recurring at regular intervals the initial dose of morphine and hyoscine is administered by hypodermic injection, an average being morphine 1/4 grain and hyoscine 1/150 grain. The indication for the amount of morphine required below this is estimated at about 1/30 grain per stone of body weight. No more morphine is given, but at definite intervals the patient is roused and shown some common object—for example, a cup and saucer—and it is then noted what her response is when asked what she has seen. This is called the memory test. No further injection of scopolamine is administered during amnesia, but when this passes off 1/450 grain is given. The full effect of the drug is obtained when there is complete loss of memory. The patient is then usually flushed and the pupils dilated. Sleep occurs between the pains, but there is restlessness and groaning while they are present. After three injections of hyoscine, which are generally at hourly intervals, a longer period should elapse before another is necessary. Fluids will be frequently taken, as the drug causes extreme thirst, and attention must be paid to the bladder.

Nembutal (capsules 1½ grains each). This is administered orally, the technique being similar to that employed in twilight sleep. The initial dose in the average case is two capsules, with subsequently one capsule at three-hourly intervals, as required.

Sodium amytal (capsules 3 grains each). This drug is not as readily excreted as nembutal, and therefore gives a longer hypnosis. The initial dose ranges from three to six grains, and is repeated as indicated.

Sodium evipan (ampoules 1 gramme to be dissolved in 10 c.cm. of distilled water). Intravenous injection is the method employed, great care being exercised in administration to ensure an efficient airway. Small doses of 2 c.cm. produce a condition of twilight sleep, and with larger doses there is complete anaesthesia for delivery.

With all these drugs there is risk of respiratory depression, and therefore respiratory stimulants, such as carbon dioxide and coramine, should be at hand. It should be more generally recognized that the only drug we have that is truly analgesic is opium. Scopolamine and the barbiturates are merely amnesic in their action. Consequently, although relief is obtained from the pains of labour, it is in proportion to the loss of memory and the degree of hypnosis that these drugs are found successful. They should never be prescribed where liver or kidney damage is suspected.

Inhalational Analgesia

Chloroform capsules (or brisettes, 20 minims of chloroform in each). One of these is crushed and inhaled by the patient at the onset of a pain. Some experience is necessary in timing the administration to obtain good results, and it is a convenient way of controlling a single dose of chloroform after the fashion of the time-honoured method of dropping the anaesthetic on the mask. As chloroform has a toxic action on the liver and heart muscle it is not recommended that it should be continued for any lengthy period.

Gas and Air Analgesia

Nitrous oxide gas is both analgesic and amnesic at the same time, and does not have any toxic effect on the patient. In my opinion the best method of giving relief is by the administration of gas and air in the right proportions. It is essential to have a reliable apparatus, which is described below.

Nitrous oxide is supplied in steel cylinders of different capacities: 50 and 100 gallon sizes are the most suitable. They are of two types: (*a*) straight valve, where the key for turning on the gas fits on the spindle at the top of the cylinder, the outlet being at the side, and (*b*) angle valve, where the spindle is at the side and the gas flows from the top. As nitrous oxide in the cylinder is a liquid under pressure of between 700 and 800 lb. per square inch, an efficient reducing valve is essential to make the gas available.

APPARATUS

This consists of the reducing valve, which allows gas to be delivered to a small rubber bag enclosed in either a metal drum or wooden box. An automatic valve causes the flow to cease when the bag is full. As soon as the bag deflates through inhalation more gas is allowed to enter. The outlet of the machine is divided into two channels—one for the passage of gas and the other for the admission of air through small holes. A check valve intermits the flow, and is only lifted when a fresh supply of gas and air is inhaled, thereby preventing an escape while the patient exhales. The whole action is controlled by inspiration. The holder fitted to the face mask has in it a finger hole, which is occluded by the patient herself, but when the finger is raised air only is inhaled. This is connected to the machine by concertina tubing. The amount of gas intermittently consumed is on the average 35 gallons per hour. In a series of private

practice cases the cost of gas averaged about ten shillings for a period of five hours. The analysis of the mixture is approximately 45 per cent. nitrous oxide in air.

Two models are illustrated: Fig. 1, size 12 in. by 8 in. by 18 in., weight about 15 lb. without cylinders; Fig. 2, size 16½ in. by 7½ in. by 4¾ in., weight without cylinder

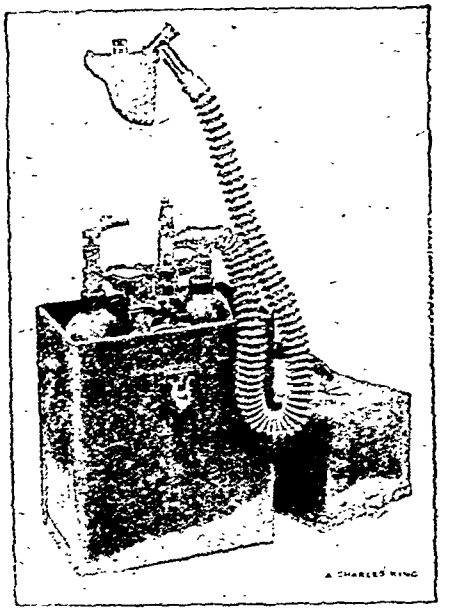

FIG. 1.

9½ lb. In Fig. 1 two straight valve cylinders are securely attached by tightly screwing up the nuts and using efficient washers, as it is essential that there should be no leaks. Only one cylinder must be turned on at a

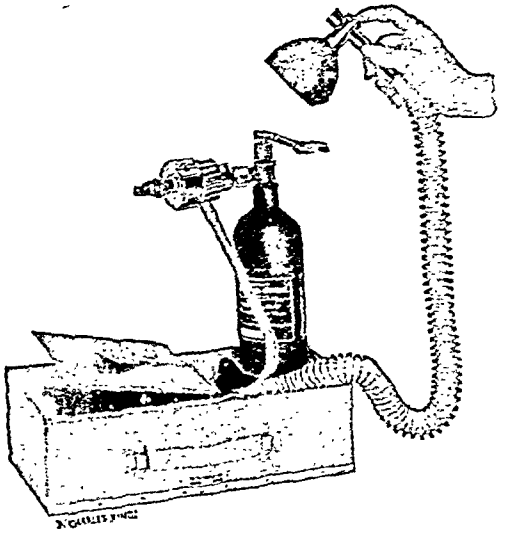

FIG 2.

time, the gauge showing when it is empty. The valve of the one must be closed before the other is opened.

In Fig. 2 one cylinder (100 gallons) stands upright in a leather pocket made for the purpose, and a reducing valve is connected to it in a similar way, a small rubber pilot bag acting in lieu of the gauge.

TECHNIQUE OF ADMINISTRATION

The patient should be thoroughly conversant with the use of the mask before labour begins, so that when the time arrives for using it she is both confident in and familiar with what she has to do. If she is at all nervous she should be reassured; and she should fully realize that the analgesia is self-administered, that she does not lose consciousness, and that it gives definite relief from pain. The mask must be applied in perfect apposition to the face to prevent air-leaks, and the finger comfortably placed over the air-hole in the correct position. Unless care is taken with these details relief will not be obtained. The question is often asked as to when the analgesia should be started. The answer is, as soon as the pains of labour cause discomfort to the patient, at which time premedication with morphine 1/6 grain is of value, if desired.

In order that the full effect be appreciated it is important that the mask be applied to the face on the slightest indication of a pain—that is, before it has become established. The patient should be instructed to inhale and exhale normally, and to increase the depth and frequency of the breathing in proportion to what she can feel. When the pain is over the face-piece should be removed. This procedure can go on with each pain for hours and until the second stage of labour. The patient can drink freely of liquids when desired, as vomiting seldom occurs.

During the second stage of labour, when the expulsive voluntary muscles are brought into play, six to eight breaths should be taken in quick succession, the patient being told to hold her breath and force down as directed. At the time of delivery, unless full anaesthesia is indicated, the patient should be continuously inhaling from the face-mask as rapidly as possible, and must be instructed not to bear down. When it is considered that gas and air is not sufficient for the delivery of the child there is no objection to following it up with any anaesthetic, such as chloroform, ether, or gas and oxygen.

POINTS TO OBSERVE

1. The mother's pulse and the foetal heart rate should be estimated hourly.

2. Normal labour is accelerated by the use of gas and air. In those cases in which advance, however slow, does not take place, and relief is not obtained, these signs should be looked upon as diagnostic and a cause sought.

The following case is an illustration.

Gas and air analgesia was administered to a patient when the second-stage labour pains had become established. For the first two hours analgesia was satisfactory, but gradually became ineffective and the pains severe. No advance was taking place in the presenting part, although full dilatation was present. Both the mother's pulse and the foetal heart rate were rising. Diagnosis: a case of obstructed labour. Treatment: under a general anaesthetic a living child was delivered by podalic version.

3. It is important to remember that cyanosis (other than that caused by holding the breath) does not occur. If any is noticed steps must be taken to find out the reason.

The following case is instructive:

A woman started the administration of gas and air analgesia towards the end of the first stage of labour. After continuing this intermittently for a few hours it was found that cyanosis was produced, and the blueness did not completely disappear between the pains. Diagnosis: an examination of the chest revealed rales and rhonchi over both lungs and oedema was suspected. This was due to a previous influenzal cold, which had settled on the chest. Gas and air was discontinued as being an unsuitable analgesic.

There are, therefore, contraindications to the use of gas and air analgesia in labour, but only in the abnormal cases. These are: (1) Patients having any heart lesion in which compensation is incomplete. Apart from the physical signs this would be shown by rapid pulse and varying degrees of cyanosis. (2) Patients with pulmonary conditions—that is, phthisis, bronchitis, and other congestive conditions of the lungs. (3) Patients with albuminuria and high blood pressure, who might possibly develop an eclamptic fit.

The apparatus was never intended for the purpose of anaesthesia, so that it is precluded in the ordinary way for any obstetric operation, such as version, the application of forceps, or extensive repair of the perineum.

TRAINING OF MATERNITY NURSES

A course of instruction in the administration of nitrous oxide and air by midwives has been inaugurated in many teaching hospitals, and when a sufficiently high standard of efficiency has been attained a certificate is issued. Consequently, maternity nurses who have obtained this certificate will be qualified to undertake the supervision of the administration of gas and air both in domiciliary practice and in nursing homes. This will enable the practitioner confidently to receive great assistance from the nurse during the earlier stages of the labour.

DETAILS OF RESEARCH

It may be of interest to record the scientific work that was carried out with the assistance of Dr. Hilda Garry in the Liverpool Maternity Hospital in March, 1934, to show that there was no danger to mother or child by the use of gas and air analgesia. Electrocardiograms were taken of a series of patients immediately before and at the end of the administration, and again a day or two later. Dr. Leslie Cunningham, medical officer in charge of the electrocardiograph department of the David Lewis Northern Hospital, Liverpool, kindly reported on these, and stated that they did not appear to be influenced to any extent as the result of the patients' experience.

The alteration in the mother's pulse and in the foetal heart rates, estimated at approximately equal intervals during analgesia, was within normal limits.

A biochemical study was made of blood obtained from a maternal vein and the umbilical cord in a number of patients immediately after delivery, with and without analgesia. The conclusions were that, although the administration of gas and air reduced the oxygen content of the mother's blood, the blood of the umbilical cord did not show any marked alteration.

In January, 1936, the British College of Obstetricians and Gynaecologists published a report on the investigation into the use of analgesics suitable for administration by midwives; in which it was stated that gas and air administered by a similar apparatus to that described was a safe and satisfactory method of producing analgesia. There were certain criticisms concerning weight and bulk, and it is highly gratifying to note that these difficulties have now been removed.

During the last three years the just demands of parturient women for the provision of the best relief available have received greater recognition. As the public grows more "gas-minded" drugs will give way to inhalational analgesia. With the further increase of interest, acquirement of knowledge, and improved organization, the means for obtaining this relief will become still more simple and expedient.

A NEW RADIOLOGY DEPARTMENT IN EGYPT

BY

R. A. GARDNER, B.Sc., Ch.M.Syd., D.M.R.E.Camb.

Director, Institute of Radiology, Egyptian University, Cairo

The Pyramids at Cairo are known throughout the world and to many they symbolize Egypt. Not so well known is the progress made in many modern spheres under the dynasty of Mohamed Aly the Great. The Ministry of Education, which recently celebrated its centenary, provides a striking example of the advance made with the help of extensive European guidance, and the development of the Egyptian University over the last twelve years has been extremely rapid. The Faculty of Medicine, which includes the old Kasr-el-Ainy school and hospital, is building on an island in the Nile what probably will be when completed the largest teaching hospital in the world. In 1922 an international competition resulted in Messrs. Nicolas and Dixon Spain of London being chosen as architects.

The foundations of the whole hospital were completed in 1930, and about 400 beds are now in use. The radiology department as planned in 1922 was found to be smaller than was required by the increase in the work. At my suggestion it was replanned in 1930, the electrotherapy accommodation removed elsewhere, and a new story added to the building. In 1932 the plan was further modified to include two wards pending the completion of the whole hospital. In 1936 a start was made by the reception of patients. In this hospital, as in Sweden, radiologists have clinical charge of beds, and forty-three beds are now (May, 1937) occupied by patients receiving treatment by radium or *x* rays, or both these agents. There are five radiologists on the staff of the department, three of whom hold the Cambridge diploma, while an assistant surgeon is delegated from the department of surgery to act as surgical specialist. In addition, radium is available to such of the surgical or gynaecologist staff as wish to employ it, but its use in this way has been mainly by the ear, nose, and throat staff.

Lay-out and Equipment

The department occupies part of the first and the whole of the second floor above the out-patient accommodation. On the first floor are situated lecture theatre, museum, photographic dark room, film stores, patients' waiting rooms, workshop, and typist and filing clerk and technicians' rooms. The second floor has the shape of a capital T, the top of which is principally for diagnostic radiology. The stem of the T is for therapeutic radiology. The diagnostic section has barium insulation and rubber flooring, and includes an electrically refrigerated dark room. All rooms used for patients (except the wards) have electric heating. There are screening rooms and two radiographic rooms. Of the four rooms three are equipped with two tables, making seven tubes in all. One of these is of rotating anode type. By means of electrically interlocked and operated switchgear, designed by me and made in Cairo by kind permission of the Director-General of the Physical Department, each of the four control tables in the four *x*-ray rooms on the low-tension side and the corresponding *x*-ray tube on the high-tension side can be connected to either a six-valve or a four-valve generator. Both generators can be employed simultaneously. This system, which is believed to be original and which saves almost the whole cost of two generators, facilitates the repair of faults, as each generator acts as a stand-by for the other. All the apparatus is shock-proof, the generators being situated in a machine room upstairs, and cables are led through the ceilings to the *x*-ray tubes. A dental apparatus of the new self-contained type is also in use for the work of the dental school.

A NEW RADIOLOGY DEPARTMENT IN EGYPT

Treatment by Radiation

For therapy a superficial treatment apparatus working at 80 kV and a short distance (Chaoul) apparatus have been in use over the past year. The latter in my opinion seems likely to displace radium for superficially situated easily accessible small growths by reason of its advantage in cost and convenience to the patient. For deep therapy at 200 constant kV there are two tubes operated from a modernized Weifa apparatus, placed in a machine room above, and a constantly evacuated tube (Metropolitan-Vickers) working at 250 constant kV. A further room awaits equipment, the 1930 plan mentioned above providing for six deep-therapy rooms. These rooms are lined with lead tiles, cast locally, and interlocked with each other. All this apparatus is shock-proof. There are also rooms for the staff and for physical and measuring and biophysical laboratories, but these latter are not yet equipped or staffed.

The two wards, male and female, of twenty-eight and fifteen beds respectively, are named in honour of Roentgen and the Curies. There is a theatre for implantation and the minor operative work associated with radiation treatment, a clinical laboratory, a radium applicator preparation room, and a radium-beam apparatus in a room adjacent to the radium safe.

The light-weight radium-beam apparatus was designed by me and made by the Solus Electrical Company, London, in 1935. Of experimental type, it will be described in detail elsewhere, but, in short, it permits the automatic electric conveyance of the radium from the inside of the safe to the patient with the operator at twenty feet distance. Here the radiation is within the assumed tolerance. The weight on the patient is only a few ounces, and movement on his part over a few inches does not alter his position with regard to the radium. Gold is used to reduce the amount of lead protection employed. The unit at present is 2½ grammes, but the apparatus has been designed so as to make later a 5-gramme unit.

Recently the number of patients treated has been at the rate of 800 per year. Most are cases of malignancy, and of these the great majority were suitable for treatment only by *x* rays. The numbers treated are increasing, and use of the "shift" system, as in many places abroad, should result in more economical use of the plants.

Progress since 1923

When I came to Egypt in 1923 Kasr-el-Ainy Hospital possessed one *x*-ray room; very little treatment was possible, and the diagnostic examinations numbered 1,600 a year only. In 1936 about 43,000 were made, principally in the old hospital. The development that has occurred has been considerable, but much remains to be done. Under the Anglo-Egyptian Treaty, so advantageous in many respects, heavy defence expenditure will be incurred and progress may be slower towards solving the problem of training the radiologists required for a population of fifteen millions and who at present number less than one per million. It will probably be many years before the chair in medical radiology approved by the Ministry of Education in December last is created in the university.

OUTBREAK OF FOOD POISONING IN LONDON

GAERTNER BACILLUS ISOLATED

On August 25 it was announced in the Press that there was an epidemic of food poisoning in St. Pancras and Finsbury, about forty cases having been traced, with one fatality. It was announced later that the source of the poisoning had been traced to a shop in Finsbury and that gammon was the offending foodstuff. An inquest was held on August 27 into the deaths of two patients thought to be due to food poisoning. The inquest was adjourned until September 2, when it was stated that H. Horsman, aged 73, and Mrs. Billingham, aged 54, had died from acute enteritis due to bacterial food poisoning, and that W. Tonbridge, aged 43, had died of acute bronchopneumonia as a result of a Gaertner infection. Dr. Albion, a medical officer of the Ministry of Health, stated that he had examined samples of cooked and uncooked gammon and other food from the shop in Finsbury and had found the Gaertner bacillus in some of the food: in a cut from the centre of the uncooked gammon there was no sign of it. For the following account we are indebted to Dr. Percival V. Pritchard, deputy medical officer of health for St. Pancras.

The Beginning of the Outbreak

A full account of the outbreak of food poisoning in St. Pancras and Finsbury cannot be recorded at this stage. Cases are still coming to notice and the investigations which must of necessity be made are still incomplete in many respects. Meanwhile a brief account can be given of what has happened in St. Pancras.

On Monday, August 23, three cases of food poisoning were notified. This is a notifiable disease in London. My inspector found a fourth case during his investigations. All four had partaken of cooked food bought on Saturday, August 21, from the same shop in Finsbury. This information was given to the medical officer of health for Finsbury so that he could deal with the shop which seemed to be the source of infection.

Three of these patients were ill within nine hours and the fourth within thirty hours of eating ham or corned beef or breakfast sausage. The symptoms were very severe abdominal pain and diarrhoea with marked prostration; vomiting was delayed for several hours and was not severe; there was a mild degree of fever.

Further Investigations

On August 24 Dr. N. D. Dunscombe, M.O.H. for Finsbury, told me about a case of the poisoning which had been brought to his notice in his investigation of the shop. This person, Mrs. S., worked in St. Pancras and lived in Islington. We found that she, her husband, and two daughters had all eaten ham bought from the shop under investigation and that with the exception of the husband they were all suffering from symptoms of food poisoning. The case was made difficult at first by the fact that the woman denied having eaten anything from the shop. This was seemingly done as an act of kindness to the shop. The truth, however, was eventually forthcoming. The daughters were at home ill and the M.O.H. for Islington was accordingly told of the circumstances. He visited and continued the survey. Mr. S. was not ill in any way, although he had had ham with his family. As a result of questioning Mrs. S. we found three more cases at her place of work in St. Pancras. These people had bought ham from the same shop on Monday evening and were ill within nine, twelve, and nineteen hours respectively after partaking of it. They showed the symptoms which have been common to most of the cases.

On Wednesday, August 25, Mr. Wilkie of the St. Pancras Hospital informed me of the death of a patient, Mr. Horsman, who had been admitted to the hospital on the previous Sunday

---

We are informed that a law to be enforced immediately in Buenos Aires will necessitate the production by the bridegroom, before marriage, of a certificate stating that he is free from any venereal disease which might be transmitted to his wife. The certificate, for which there is no charge, is to be presented to the civil authorities. The law does not apply to women, and includes clauses providing for the closing of houses of ill fame and for the "compulsory hospitalization of refractory cases of contagious infection."

with severe enteritis. His examination of the stools had progressed as far as demonstrating the presence of a non-lactose fermenting organism. This pointed to the possibility of infection with *B. typhosus* or other organisms of the Salmonella group which could account for the enteritis. Mr. Wilkie had been given a history of eels in his patient's diet. I decided to investigate this.

The situation at that time was as follows: We had no evidence of any cases being connected with the shop beyond our original four notifications. There were three distinct investigations proceeding in connexion with enteric fever—missed, suspected, and actual—in the borough. There was a small, well-confined outbreak of ten cases of food poisoning in an institution.

On investigation at Mr. Horsman's lodgings it was found that he had eaten ham from the shop on August 20 or August 21. He lived alone in a furnished room. He was ill on August 22, and his doctor sent him into St. Pancras Hospital late that day. We obtained the ham which remained and had it examined bacteriologically at University College Hospital. The final report on that was: no typhoid, paratyphoid, or dysentery bacilli; no organisms of the food-poisoning group were isolated, such as *B. gaertner, B. aertrycke,* or *B. newport*; no other abnormal coliform organisms isolated. On culture there was a very marked growth of staphylococci, 10 per cent. of which were *S. aureus* and 90 per cent. *S. albus.* A growth of non-haemolytic *Streptococci mitis* was also obtained. At the same time as this investigation led us so directly to the suspected ham and suspected shop, Mrs. S. admitted the connexion there and the other cases were brought to light.

The fact that a food poisoning outbreak had actually started was now evident. Doctors working in the affected area were immediately informed of this. Some doctors had already met the epidemic and were able to make a diagnosis of cases which had puzzled them. We followed up these cases at once from lists supplied by the doctors, and were able in that way to trace the food eaten, in all except one case, to some connecting link with the Finsbury shop. It will be seen that cases came under notice in various ways: statutory notification, notice by patients' letters, and in the course of investigating other cases. The epidemic is not yet fully explained. There has been no time. These brief facts and questions may produce interest and may be answers to some of the problems which the outbreak has produced.

The Question of "Toxin"

Gaertner bacilli have been isolated in a number of the stools. One man was ill within five hours of eating the ham. Other patients were ill within eight and nine hours. Most of them took twelve hours and more. The question arises, Can a Gaertner infection be followed by enteritis in the short space of five hours? Was there a massive dose of preformed toxin in the meat? The following case is interesting. Mrs. C. bought some breakfast sausage from the shop and gave it to her two sons. She is quite certain she had none of the food herself from that place. The three were taken ill at the same time and she was removed to hospital. Her stools were very carefully examined, but no Gaertner organisms were found. Were these cases affected by toxin? If so, it must have been very potent to act in the way it did. In several cases where groups of people, say a family, were affected it has been interesting to relate the amount of the suspected food eaten with the severity of the illness. The rule seems to have been that the more eaten the greater the degree of attack. This was shown in two groups by the number of "poisoned" sandwiches eaten. These and the many other interesting points which have arisen in connexion with this epidemic will receive further consideration, and will no doubt form the subject of a complete report at a later date.

The Duke of Kent will open the new radiological department of the North Staffordshire Royal Infirmary, Stoke-on-Trent, on October 13. The department has cost £24,000, of which £11,000 was given by Mr. G. H. Downing, a former High Sheriff of Staffordshire.

POSTGRADUATE MEDICINE

THIRD INTERNATIONAL CONGRESS AT BERLIN

We are indebted for the following account to Colonel A. H. Proctor, D.S.O., M.D., Dean of the British Postgraduate Medical School, Hammersmith.

The Third International Congress on Postgraduate Medical Education began on August 21 in Berlin. There have been two previous congresses on postgraduate medical education, the first in 1909 in Budapest, and the second in London in 1913. Since the war no further congresses have been held. This year's congress was organized by Professor Adam, a member of the original committee, and Secretary General. The German Government gave generous help and assistance, and the meeting was presided over by Dr. Kurt Blome, the director of postgraduate medical study appointed by the Reich medical leader. The congress met in the large hall of the Langenbeck Virchow House, and the interest aroused is shown by the fact that although the hall will seat 700 people extra chairs had to be brought in. Forty countries were represented, France by no fewer than eleven delegates and Japan by nine.

Dr. PFUNDTNER, Secretary of State for the Interior, who formally opened the congress on behalf of the Reich Minister of the Interior, Dr. Frick, who was unable to be present, referred to the influence of such meetings in promoting international good will and friendship.

The Doctor in Modern Germany

The Reich medical leader, Dr. WAGNER, then read a paper on "The Position of the Doctor in the New Germany." He opened by stating that the doctor's chief duty was to combat those conditions "which history shows have caused nations to perish"—namely: (1) the decline of births; (2) the swamping of the best and most capable parts of a nation by those elements which had no right to existence; (3) the mingling with the blood of a different race. The chief task of the German doctor lay in promoting all measures which would strengthen the health and vigour of German individuals. He outlined the scheme by which a medical survey of the whole working population was to be carried out and early departures from normal health recognized and treated. In future each German was to get a medical certificate which would record all medical facts of importance from birth to death. (Free choice of doctor was insisted on.) The new "Reichsärzteordnung" of April 1, 1936, fixed the rights and duties of the German medical man. It was a legal duty for him to support the steps taken by the State and party in the sphere of population and health policy. The profession of a doctor was no longer a trade in Germany, but a public task settled by law. The "Chamber of Doctors" (Reichsärztekammer) controlled the medical profession. It could distribute doctors systematically over the country and prevent, if necessary, the setting up of practice in places whose requirements were already provided for. Postgraduate education was no longer left to his discretion. It was his duty, and only teachers were exempt from such courses. The Chamber also had full disciplinary powers. Permission to join the panel under the insurance scheme was given by committees consisting of doctors appointed by the K.V.D., a special corporation including all doctors on the panel. It was to this body the panel doctor was accountable for the fulfilment of his contract, and this corporate body was responsible to the insurance organization for the orderly and good medical treatment of the insured person.

Postgraduate Education in Germany

In a paper on research and postgraduate study Professor BORST of Munich put forward a strong plea for free and independent research—that is, research which had no particular aim other than to determine true relationships. Only in times of stress and in emergencies could the research worker be assigned special problems. He stressed the necessity of training the rising generation. Research, instruction, and medical postgraduate study were inseparably related. Postgraduate courses must include the progress made in the natural sciences and in biology. Research was essential for the good physician, and must find a place in all sound proposals for postgraduate education.

The organization of postgraduate study in Germany was described by Dr. BLOME. Intensive refresher courses for all doctors were now compulsory once in five years. In 1936 4,941 doctors attended such courses. The number of doctors attending each course was limited to twenty, and postgraduate centres had been established in sixty-eight centres. Country practitioners attended for three weeks, but medical men residing near centres could take evening courses over a longer period. These were not regarded as so satisfactory. At each centre a director had been appointed whose duty it was to organize courses in co-operation with the instructors and in accordance with the general principles laid down. Fees were charged for the courses and had to be paid by the doctors themselves; assistance was provided for those who needed it. Advanced study was basically international in character and was guided by the Academy for Medical Postgraduate Study. This was given in a university or an academy. For example, Munich academy was devoted more especially to the physiology of work, and in Dresden studies were conducted in nature courses, spa treatment, fasting, and other forms of treatment which had been largely in the hands of non-medical healers. These courses were now sponsored by the medical profession and not, as formerly, by the administrative authorities of bathing resorts and spas. Special courses were held at Alt-Rehse, where there was a school for leaders of the medical profession. (By "leaders" are meant leaders for the organization of health policy in accordance with present political ideals in Germany.)

Dr. Blome was followed by Professor OBERLING of the Medical Faculty, Paris, who gave a survey of medical postgraduate study in France, and a further paper on the importance of pathological anatomy for postgraduate instruction. Speakers from Austria, Japan, Italy, Switzerland, Greece, and Poland each in turn described postgraduate facilities available in their respective countries.

The "New" German Medicine

On Monday, August 23, the congress opened with a paper by Professor GROTE, Superintending Physician of the Medical Clinic of the Rudolf Hess Hospital at Dresden, on the "New German Medicine in Postgraduate Study." Professor Grote's paper was a little difficult to follow. It indicated that the new German medicine had acquired a new outlook in two directions. First, it was concerned with the diseased conditions in racial and national life, and therefore devoted its attention to problems of heredity and the conclusions to be drawn from them. From this had arisen the new marriage laws and prevention of hereditary disease. Secondly, in the past German medicine had been mainly concerned with the cause and mode of origin of symptoms in an attempt to attain ideal therapy by treating the cause. German medicine to-day was engaged in the interpretative analysis of symptoms and their significance, and in the region of therapy was investigating dietetic and physical procedures which had met with success in the treatment of disease.

Colonel A. H. PROCTOR, Dean of the British Postgraduate Medical School, London, read a paper on the British Postgraduate Medical School and the necessity for separating postgraduate from undergraduate teaching. He referred to the part played in postgraduate education by hospitals devoted to special diseases.

Postgraduate Training in Obstetrics

Professor WAGNER of Berlin and Professor VAN ROOY of Amsterdam read short papers on the particular difficulties of postgraduate study in obstetrics. Each reviewed briefly the conditions for the training of students, and suggested that this should extend over several years. Postgraduate training in obstetrics was even more difficult as it had to be crowded into a short space of time. Professor Wagner considered the problem hard to solve in countries where delivery in the home with the aid of a midwife and eventually a general practitioner or a specialist was advocated. He recommended the utilization of large public lying-in hospitals which did not serve any other educational purpose. All physicians engaged in the practice of obstetrics should be compelled to attend postgraduate courses periodically.

Surgery, Tropical Medicine, Radiology

Professor SAUERBRUCH, Director of the University Surgical Clinic, Berlin, in a paper on postgraduate study in surgery, stressed the difficulty of training in operative surgery and the necessity of illustrating the principles of surgery in simple cases.

Professor MÜHLENS, Director of the Tropical Institute, Hamburg, said that the courses held there included a special nine weeks' course, at the end of which an examination was held and a diploma granted. Other courses provided were: one in Spanish, a special course for ship surgeons, courses for candidates for the degree of doctor of medicine, and for assistantships in various laboratories and in the tropical hospital. As many as 300 or more students attended during the year from all parts of the world.

Professor HOLTHUSEN of Hamburg, in a paper on diagnosis and therapy by radiation, drew attention to the fact that various specialists used *x* rays in their clinical work, and many general practitioners were also more or less active in this field. Efforts were now being made to induce more practitioners to take up radiology as a special subject. Measures for training the rising generation of doctors had not kept pace with requirements.

Postgraduate Study in Psychiatry

Professor KLAESI, Director of the University Psychiatric Clinic in Berne, in an interesting paper on postgraduate study in psychiatry, referred to the loss of the old family physician, who was helper and counsel not only in disease but also in the emotional and moral problems of his patients. One-sided thinking in the natural sciences had led to the functions of the old family physicians being taken over by "occupational" and "matrimonial" advisers, "psychotechnicians," and quacks. The student should be stimulated to take an interest in psychiatry and in the wider study of human conduct. He ... that facilities for postgraduate study in psychi...

be provided by properly edited periodicals, evening clinical demonstrations for general practitioners, and vacation courses.

Dr. ENGEL of Berlin, discussing the importance of postgraduate study for the State and those who administered insurance, pointed out that there were 20,000,000 insured persons in Germany, and their healthy working power was a most precious possession. The influence of medical progress affected not only the present but future generations. He stressed the great importance of postgraduate study in industrial organization in raising earning power, in providing occupational welfare work, and in the prevention of disease and the treatment of accidents.

The Cancer Campaign

The morning of Tuesday, August 24, was devoted to the campaign against cancer and its importance as a subject of international postgraduate study. The discussion was introduced by Dr. SCHRAENEN, Secretary of the Belgian Society for the Combating of Cancer, and by Professor AULER, Secretary General of the German Commission. Other papers were contributed by Professor FISCHER, Rostock; Professor KÖNIG, Wurzburg; Professor SCHRÖDER, Leipzig; Professor HAUBOLD, Berlin; and Professor REDING, Brussels.

Dr. Schraenen said that the object of the campaign against cancer was to give the best possible treatment to the greatest possible number of patients at the earliest possible stage of the disease. In order to achieve this ideal the following demands must be met. The public should have a basic knowledge of the nature of cancer, know what methods existed for fighting it, and above all must be persuaded of the importance of their own co-operation in this struggle. The diagnosis of cancer must be so organized that the disease might be definitely recognized as early as possible. Opportunities for suitable early treatment should be assured. For subsequent treatment there must be a service of supervision, and also a "social cancer welfare" organization devoting itself to the economic and psychological consequences of cancer for the patient and for his family. The measures required for this were the special scientific training of medical students in relation to cancer; a constant reawakening of the interest of practising physicians (for example, by making available to them treatises on the progress of cancer research, by courses, by postgraduate lectures); close co-operation of physicians in dealing with individual cases through the welfare service of the cancer league; co-operation between the medical profession and the anti-cancer centres (institutions which unite all the measures for dealing with cancer—diagnosis, therapy, research, and instruction). The practical side of the question, which had been recognized by all as being of the utmost urgency, had not been tackled.

Professor LAMBADARIDIS of Greece said that in Greece the mortality from cancer was probably higher than in any other civilized country. The total population was about 7,000,000. He estimated that about 350,000 were suffering from cancer. Statistics, however, were for various reasons lacking. This year an institute for cancer research had been established from public and private funds, but there was a serious lack of doctors with special training. Examination stations should be established which the entire population should be compelled by law to visit at regular intervals. The family doctor had an important part to play in the fight against cancer, especially in early diagnosis. Professor Lambadaridis's proposal that the family doctor should remove biopsy specimens for diagnosis, although it may not be approved in this country, may, with the conditions of practice in Greece, be necessary there. In Greece it may be impossible to obtain the opinion of an expert in these cases or to send them to a hospital until their diagnosis is confirmed.

Professor SCHRÖDER of Leipzig described the part the general practitioner could play in the campaign against uterine cancer. He advocated written and pictorial propaganda, exhibitions, and instruction by social workers, community nurses, and midwives.

Films in Education

On Tuesday Dr. KITTLER read a paper on the use of films in postgraduate study. Some excellent films illustrated the indications for the administration of insulin in diabetes. So far as major surgery was concerned, it was thought that films could only serve to broaden the therapeutic range of vision of the general practitioner; they were not of much use in teaching operative surgery. Interesting films of the mechanism of labour, made up in the same way as the well-known Walt Disney films, were also shown.

An International Academy for Postgraduate Work

On Tuesday afternoon a special meeting of the International Congress of Postgraduate Medical Education Committee was held, and a proposal was brought forward to establish an international academy of postgraduate work and research. The draft constitution and statutes were submitted and a prolonged discussion took place on the various proposals contained therein. The object of the academy is to foster medical postgraduate work and research on an international basis; to make accessible to all the other members of the academy the achievements of the various countries and their investigators, both in general medicine and in its special branches. Its duty would be to organize postgraduate courses, study-meetings, and congresses; control the exchange of teachers and students of every affiliated country; to offer opportunities for advanced and postgraduate study in each country; to arrange study-tours in foreign countries; to improve methods of teaching, especially with regard to the use of films; to translate and distribute publications of special importance from distant places; to help to finance important research; to impart information about the particular problems of various countries and their branches of research; to distribute and advise doctors of affiliated countries, groups, and special groups.

It is proposed that a permanent bureau should be set up in Berlin, and the general organization was outlined. The approval to establish such an academy was carried by a large majority and the draft constitution and statutes were referred to a smaller committee. Such an academy would serve a very useful object not only in promoting medical progress but in furthering international fellowship and friendship.

Facilities for the Foreign Doctor in Germany

Wednesday, the concluding day of the congress, was opened by a paper by Professor ADAM of Berlin, on the opportunities for advanced study for foreigners in Germany, such as: (1) posts as voluntary assistants in clinics and institutes, the smaller universities being best suited for this; (2) the international postgraduate courses in March and October for specialists in their given fields;

(3) courses in Spanish specially designed for Latin-American students. Professor Adam also described the various organizations which gave special aid to foreign physicians. These included: (*a*) the Information Office of the Kaiserin Friedrichhaus, Berlin; (*b*) the Foreign Section of the University of Berlin Staff Association; (*c*) the Institute for Foreigners in the University of Berlin, devoted chiefly to teaching the German language to foreigners; (*d*) the America Institute; (*e*) the Japan Institute; (*f*) the German Academic Exchange Service, an organization which arranges exchange positions for German and foreign physicians: with its Humboldt Foundation it is in a position to grant fellowships to foreign physicians during their stay in Germany.

Dr. KENNEDY of Cornell University, New York, then began a general discussion on the international exchange of instructors and students, in which a number of delegates took part.

Industrial Medicine

A discussion on instruction and postgraduate study in industrial medicine was introduced by Dr. BAADER, Director of the University Institute for Industrial Medicine. Stressing the necessity for special study in this particular branch of medicine, he pointed out that in Germany this was a post-war development and that rapid mechanization and technical processes had resulted in the manual labourer being worn out at the age of 45 to 50. In Berlin there was a university institute for occupational diseases. At Munich there was an institute for the physiology of work and a pathological institute for industrial and accident hygiene. In the Ruhr district several hospital departments were engaged in the study of pneumonoconiosis, etc. Besides these, special clinical departments in industrial hygiene are provided at the Reichsgesundheitsamt, the Workers' Protection Museum in Berlin, the Museum of the German Society of Workers' Protection in Frankfort-on-Maine, and the Bochum Museum of Mining.

Dr. E. L. MIDDLETON, one of the English delegates, described the education in industrial diseases that is provided in England, and a number of other physicians from Paris, Italy, Brussels, and Buenos Aires took part in the discussion.

W. Haupt (*Med. Klinik*, July 16, 1937, p. 957) cites comparative statistics of mortality from cancer in different countries. For each 10,000 inhabitants 13.4 died of cancer in Germany and 15.3 in England. The general mortality for each 10,000 inhabitants was 107.8 for Germany and 124 for England. However, there is no connexion between general mortality and mortality from cancer. In Chile, for example, the general mortality is 267, while the mortality from cancer is only 7.2. The mortality from cancer in Germany is higher for women than for men, the proportion being 121 to 100. The proportion is much higher in the United States—namely, 220 to 100. Cancer of the genital organs accounts for one-fifth to one-quarter of all cases of cancer in women, and 60 per cent. of all cases occur in women under the age of 50. Unfortunately a large proportion, varying from 42 to 82 per cent., neglect to seek medical advice until it is too late. The author recommends a number of measures for the campaign against genital cancer, the most important preventive measures being voluntary regular yearly examination of all women over 35 years of age and supervision of all cases already treated. Finally, he cites statistics relating to the results of treatment of carcinoma of the uterus in its different stages.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

THE NOTTINGHAM MEETING

The British Association met at Nottingham this year from September 1 to 8, under the presidency of Sir EDWARD POULTON, F.R.S., and full accounts of its activities have appeared in the daily press. We give here a brief summary of one or two of the subjects discussed at the meeting.

The Presidential Address

The wide general interest in scientific progress to-day is in marked contrast to the antagonistic attitude displayed by other branches of learning as recently as a century ago. When, at the Oxford meeting of the British Association in 1832, honorary degrees were conferred on David Breuster, Robert Brown, John Dalton, and Michael Faraday, current opinion was reflected in a letter from John Keble to a friend: "The Oxford doctors have truckled sadly to the spirit of the times in receiving the hodge-podge of philosophers as they did." The doctrine of evolution probably stirred more widespread opposition than any other scientific advance. In surveying the history of evolutionary thought in the presidential address to the British Association at Nottingham, Sir EDWARD POULTON traced its progress as it may be followed in the series of meetings of the Association, dating as far back as 1881, with which he has himself been personally concerned.

At the Jubilee meeting of that year the outstanding event was Huxley's evening lecture on "The Rise and Progress of Palaeontology," the foundation upon which geographical, geological, and biological evolutionary history had been built. It was surprising to reflect that many of the older naturalists, even so late in the Victorian era, had found almost insuperable difficulty in believing that the land had been for the most part deposited under the sea, or in accounting for the presence of fossils, "formed stones" as they were called in those days. Huxley cited the work of Nicholas Steno of Florence, published in 1669, concerning certain fossils of the Tuscan rocks, known as glossopetrae, and commonly believed to be fossil fig leaves. By dissection of a shark's head Steno showed the complete correspondence between the "glossopetrae" and the shark's teeth—"that in fact they were shark's teeth." Surveying Steno's further studies of Tuscan fossils, proving their relationship to terrestrial, fresh water, and marine organisms, studies later extended over a wider area by Button, Huxley envisaged the framework of palaeontology as thereby completed save for one component. This was supplied towards the end of the eighteenth century by William Smith, who showed that rocks of the same age were identifiable in all parts of the world, while the biologist could follow the changes in living organisms, constituting a record of constant extinction and continual regeneration of new species.

Following the establishment of the conclusion that life has existed in this world over a vast period of millions of years, discussions regarding the actual age of the earth continued intermittently at British Association meetings from 1892 until 1921. It was a matter of difficulty to reconcile the conclusions reached by exponents of different sciences. Thus the physicist, Lord Kelvin, estimated a hundred million years as the period during which the earth had been sufficiently cool to support life, an estimate later reduced by Professor Tait to ten million. The geologists and biologists, however, maintained that an immensely longer period was required for the history of fossiliferous rocks and the evolution of animals and plants. In 1896 the

physicists were disagreeing among themselves, Helmholtz allowing the sun eighteen million years for giving out radiant heat at its present rate, while Kelvin allowed 500 million. Sir George Darwin, who concurred with Kelvin, nevertheless drew the reasonable conclusion that "the physical argument is not susceptible of a greater degree of certainty than that of the geologists, and the scale of geological time remains in great measure unknown." Again, in the words of Sir William Turner at the Bradford meeting in 1900, the birth of this world "must have been in the far-distant past, at a period so remote from the present that the mind fails to grasp the duration of the interval."

Discussing organic evolution, the President threw some light upon the reception of Darwin's *Origin of Species* by the laity, showing that the clergy especially were less antagonistic than was generally supposed. He was himself present at the Church Congress at Reading in 1883, and recalled the unanimous enthusiasm with which the audience received a paper by Aubrey Moore on "Recent Advances in Natural Science in their relation to the Christian Faith." Nevertheless, the new conceptions were not easily assimilated. Contemporary comment some twenty years earlier, in 1861, was illustrated by the verse:

> "A deer with a neck that was longer by half
> Than the rest of its family's (try not to laugh)
> By stretching and stretching became a Giraffe,
> Which nobody can deny."

With regard to acquired characters, maintained by Weismann to be incapable of hereditary transmission a statement accepted by nearly all biologists, the President suggested that this vital conclusion was insufficiently appreciated by the general public. He adduced in support the opinion of the late A. A. Macdonell, Professor of Sanskrit at Oxford. The professor, who spoke both English and German as they are spoken by "natives," held that it was impossible for any mature person to learn a foreign language to this extent. Familiarity with a language in early childhood was the essential basis. Yet any human being transported in infancy from his own country to another, and brought up there among the natives, could learn to speak the language as spoken by the inhabitants. Nor would the fact that his forbears, perhaps for many generations, had spoken the language of his birthplace retard or modify his acquisition of another tongue under these conditions. "Educability" could be transmitted; it was a congenital character. But the results of education could not be transmitted. With further reference to the inheritance of acquired characters the President described the elaborate adaptations by which sedentary insects were hidden from their enemies, adaptations evolved not by experience but by avoidance of these enemies. For instance, a twig-like caterpillar, resting on a branch in close proximity to a wren's nest, was unnoticed by the bird, which, however, immediately saw and devoured it when it was placed on a white surface. Sir Edward recalled Lord Lister's presidential address in 1896, a simple and modest record of the great benefactor's life work, and an enduring inspiration to those privileged to be present.

The Sex Ratio

In a paper on the sex ratio Professor F. A. E. Crew, President of the Section of Zoology, maintained that the *Statistical Review of the Registrar-General* was a zoological contribution of surpassing interest. It was, in fact, a progress report of a vast and exciting zoological experiment which we are conducting, scientifically or otherwise, with ourselves as the experimental material. For the correct interpretation of many of its data knowledge derived from the study of lower forms of life was essential. This was particularly apparent in the human sex ratio. In the case of man the male was shown to be less viable than the female. Especially was there a general proneness on the part of male infants to die in greater numbers, irrespective of the cause of death. It was necessary, therefore, to decide what fundamental differences between the sexes might be responsible for this variation in viability. Males differed from females in genetic constitution. The male was heterogametic, the female homogametic, and the higher mortality of the heterogametic sex had been amply demonstrated among wild populations. Males were predominantly catabolic, females anabolic. Males showed a higher metabolism rate, a higher erythrocyte count, a higher haemoglobin value. Experiments in male pigeons showed that their basal metabolism was more easily and more deeply affected by conditions of high temperature or low oxygen supply than that of females. Males of the sword-tailed minnow were more susceptible to alcohol, potassium cyanide, and extremes of temperature. The higher metabolic rate of the male appeared to render him less resistant to unfavourable conditions and more prone to death.

Figures relating to farm animals showed without exception that the males among them shared the relative frailty of the human male, and records of laboratory rats and mice told the same story.

Generally among birds the female was found to be more fragile. Pre-natal death fell more heavily on female fowls. The males of the Japanese turtle dove appeared to be the longer-lived. But in birds the heterogametic sex is the female.

Evidence derived from fish was of less value, for the sex chromosome constitution had not yet been fully determined. A wide range of observations upon insects showed that the male, whether homo- or hetero-gametic was the shorter-lived.

There was nothing unique about the human sex ratio and the factors which operated to distort it were exactly those which produced the same results in other forms of life. The problem must be studied not only in the office of the statistician but also in the laboratory of the experimental biologist and in the open country, with the collaboration of the physiologist and the geneticist.

Heat Production, Nutrition, and Growth

Dr. E. P. POULTON, President of the Section of Physiology, prefaced his address on heat production, nutrition, and growth in man with some practical comments on the question of medical research. In recent years facilities for whole-time research had enormously increased, and such benefactors as Lord Nuffield had largely contributed to this happy state of affairs. It was important, however, to make provision for the research expenses of those willing and able to devote their spare time to such work in the course of teaching and practice. Dr. Poulton stressed the lamentable time lag between the publication of new methods and their general adoption. If a new form of therapy were available in pill form, its widespread application was rapid and assured. If it involved the purchase of apparatus or other difficulties, it might remain neglected for years in many parts of the country. This was attributable to the straitened financial circumstances in so many voluntary hospitals. Money was indeed urgently required for popularizing the results of research. Voluntary hospitals, which naturally hesitated to buy expensive apparatus, would not be slow to use it if provided free of cost. By applying this principle, in the first instance, to the voluntary teaching hospitals, thus accustoming medical students to new methods and new apparatus, the dissemination of the knowledge of fresh advances would spread rapidly throughout the country. Following a

thorough survey of methods of direct and indirect calorimetry, Dr. Poulton advocated the theory of the constant combustion ratio: that carbohydrate and fat are always burnt in the body in a fixed proportion, and the respiratory quotient, when it is high, measures the amount of conversion of carbohydrate into some less oxygenated material such as fat, and when it is low, measures the reverse change. Such a theory was far from unreasonable, for other quantities associated with the human system—for example, body temperature and hydrogen in concentration of the blood—varied only within comparatively small limits. As an illustration, the story of Cain and Abel suggested that the diet of primitive man was variable in its carbohydrate and fat content, the choice of food being influenced by the exigencies of hunting and cultivation. It was not reasonable to suppose that the complicated processes of human metabolism should be at the mercy of such extraneous circumstances. It was more logical to assume that such processes normally followed well-defined lines of chemical and physical action, while any foodstuff taken in unusual quantity was converted into a form suitable for storage for future use. With regard to standards of metabolism, growth, and general nutrition in children, Dr. Poulton suggested that there was some factor in modern life that tended to promote growth in the children of the wealthier classes. This factor was lacking in all classes fifty years ago, and was still absent among the poorer classes to-day. Since heredity could scarcely be a predominant influence, the cause might be attributed to alteration in the food supply, involving an increase in minerals and vitamins.

Hypnosis and Suggestibility

Before the Section of Psychology Dr. WILLIAM BROWN read a paper on hypnosis, suggestibility, and progressive relaxation. Dr. Brown affirmed that recent experimental and clinical work had established hypnosis on a firm scientific basis. In the treatment of patients the employment of hypnosis resulted in a more rapid and more pronounced induction of relaxation. It was important that any suggestions made to patients in the hypnotized and relaxed state should be positive in character, tending to increase normal vitality and vigour. By this means concentration, memory, and mental powers could be improved, and inhibitions and the fear of failure removed. With regard to variation in susceptibility to hypnotism, Dr. Brown stated that cases of idiopathic epilepsy and *petit mal* were not responsive, and that induction was difficult in persons suffering from extreme fatigue. Alcoholism and scopolamine increased susceptibility, while cases of so-called hysterical epilepsy were especially amenable to hypnotic treatment. Recent work in the United States had shown that new conditioned reflexes could be built up more rapidly and thoroughly under hypnosis than in a normal state. This opened up the possibility of improving the digestive and excretory functions, by extending the power of the will to influence involuntary actions. The therapeutic hypnotist must not be regarded as dominating his patient, but rather as using his influence to inspire confidence and faith. Dr. Brown compared this relationship with that of people and leaders in political affairs.

"Whatever opinions may be held with regard to the political aims of the Fascist countries, there can be no doubt that the methods adopted in Germany and Italy of attaining efficiency as a nation under individual leadership find a great deal of support in modern psychology. It is a mistake to suppose that the followers in these countries are slaves, copying their leader from a motive of fear or in cringing submission; rather do their own self-assertive and aggressive tendencies become liberated in the process, and their heightened enthusiasm and confidence in their leader and his resources make what might have been a timid, panic-stricken crowd into a powerful army, race, or nation."

Local News

ENGLAND AND WALES

Pharmaceutical Society's New Home

Plans for the new home of the Pharmaceutical Society of Great Britain have been passed by the London County Council, building operations will start shortly, and the Society expects to enter into occupation in 1939. The site is the north side of Brunswick Square, overlooking the Foundling grounds, and within five minutes' walk of Upper Woburn Place and the British Medical Association House. The architect's perspective shows that a spacious and dignified building is in contemplation. It will have six floors, and will embody an assembly hall, library, lecture theatres, laboratory accommodation and class rooms, council chamber and committee rooms, and full provision for the administration and publication departments, which are at present rather scattered in Bloomsbury Square. Chiefly with a view to harmonizing with the Victorian character of the new locality, the façades will be of brick, with an unusual and pleasing treatment of the principal frontage. To the right of the vestibule on entering will be the assembly hall, extending to the height of two floors and seating from 350 to 400 persons; to the left will be the library, also two stories in height, with embayments in which small tables for readers will be placed. Directly facing the vestibule will be a lecture theatre, accommodating 250, with provision for up-to-date cinematograph and other demonstrations. This will be flanked on each side by an open court, permitting cross-lighting of the assembly hall and library. A members' lounge and writing room are also to be provided, and on an upper floor council and committee accommodation. The Pharmaceutical Society is more than a professional body: it incorporates a college, which is a school of the University of London in the Faculty of Medicine, with 100 students, and to this college will be devoted the whole of the third and fourth floors in the new building. There will be a large dispensary, departments for advanced and physical chemistry, bacteriology, and research, a small-scale manufactory, and a galenical department. Tutorial and service rooms, a second lecture theatre, a curator's room, staff rooms, and workshops will complete the provision for the school. Examination rooms are to be placed against the respective departments throughout. The top floor is to be devoted to pharmacological research, with a nutrition department, various animal rooms, and histological and chemical laboratories. Another department for which provision is to be made is pharmacognosy, or the science of crude drugs. Altogether the building will form another conspicuous addition to the collegiate and research centres which are multiplying in Bloomsbury within a half-mile radius of the central tower of the University now approaching completion.

L.C.C. Hospitals and Health Services

A year ago the London County Council approved a proposal to engage, for an experimental period of twelve months, two part-time obstetricians and gynaecologists for duty at four selected hospitals. The experiment has proved satisfactory, and the scheme is to be extended to certain other hospitals with large and growing maternity and gynaecological units. The hospitals participating are Dulwich, St. James, Lewisham, St. Giles, St. Alfege's, St. Mary Islington, Archway, and Highgate. The capital expenditure on hospital services under the London County Council for the year 1937–8 is estimated at £650,000, the same amount as last year, but greater than any other previous year. The many important schemes of extension

and development authorized by the Council and in process of being carried out include several for the provision of additional accommodation for patients, new nurses' homes and extensions of existing homes, and various other plans for improving present conditions. A sum is included for preliminary expenses in connexion with the new general hospital of about 500 beds to be erected on part of the site of St. Benedict's Hospital, Tooting, to meet the demand for additional accommodation in the south of London. The estimated cost of the maintenance of L.C.C. hospitals for 1937–8 is £5,395,820, some £200,000 more than the estimated expenditure for 1936–7. The after-histories of tuberculous patients five years after they have been discharged from L.C.C. institutions are published from time to time. The latest survey deals with patients who were discharged in 1931. The number of adult patients discharged from residential institutions in that year was 4,368. In 554 cases the diagnosis of tuberculosis was not confirmed, 344 cases could not be traced, and so the number of cases investigated was 3,470. Of the early cases of pulmonary tuberculosis 77.3 per cent. were alive after five years; of the moderately advanced cases, 44.1 per cent.; of the advanced cases, 7.8 per cent.; and of the cases of surgical tuberculosis, 74.1 per cent. During the same year 884 children were discharged; and a report is available as to 595 of these (170 pulmonary and 425 non-pulmonary cases). Of the early pulmonary cases 10.3 per cent. had died; of the moderately advanced 66.7 per cent., and of the advanced all had died; of the non-pulmonary cases 8.5 per cent. had died. The number of patients under reception orders in the L.C.C. mental hospitals at the end of the last six-months period (March, 1937) was 21,013. During the six months 443 were discharged recovered, 334 relieved, and 81 not improved, while 669 had died. The number of voluntary patients in residence was 877, and the number of temporary patients 37.

Food Investigation

The Report of the Food Investigation Board for 1936 states that the year has been one of great activity, marked especially by the meeting of the British Commonwealth Scientific Conference and by the Seventh International Congress on Refrigeration. An investigation of the identity and properties of the proteins of muscles has resulted in the isolation of a new fraction, myoalbumen, which is interesting on account of its low iso-electric point (3.0 to 3.5). Myoalbumen constitutes 1 per cent. of the soluble proteins of rabbit's muscle. The report for 1935 referred to the high electrical resistance of the carcasses of pigs which had been overheated before slaughter (*Journal*, October 31, 1936, p. 877). It has since been found, in the course of experiments carried out for the Pigs Marketing Board of Northern Ireland, that the hams made from such carcasses show an unusually high incidence of taint. Conversely, low electrical resistance of the muscular tissue before curing is generally associated with a low incidence of taint. Thus it appears probable that measurements of the electrical resistance of the uncured carcass may be of use in forecasting the incidence of taint in hams. It has been established that herrings cured with much less salt than is now employed in the trade keep well for six months at the usual storage temperature of −3° C. Experiments in progress point to the possibility of small amounts of formaldehyde being present in bound form in the flesh of fresh marine fish, and, to a greater extent, in salt-cured and dried fish. The origin of the formaldehyde is being investigated. The rancidity which develops in herrings' fat during cold storage is due to certain enzymes, which are activated by common salt. In the case of fresh herrings, brine-frozen and subsequently well washed, only slight oxidation of the fat was observed after six months' storage in boxes at −28° C.; with smoke-cured fish lowering the accepted storage temperature (−8° to −14° C.) to −20° to −28° C. has been followed by an improvement in the quality of the fish, due to a retardation of deterioration. The report also records a special method, introduced in Belgium, applicable to the commercial cold storage of hot-house grapes, whereby water is supplied to the bunches during storage. Laboratory trials of this technique have shown promising results in the case of English muscats. A comprehensive series of experiments has proved that Victoria plums may be stored for three to four weeks at a temperature of 32° to 34° F. If the fruit is sufficiently mature when picked it ripens well after cold storage at any temperature from 50° F. If picked too green a really good quality cannot be attained, but an improvement in both colour and quality may be produced by ripening at 70° F. The report also mentions the possibility of increasing the home production of pears, which respond even more favourably than apples to gas storage. The value of pears eaten annually in the United Kingdom is roughly £2,000,000. The proportion of home-grown pears was 29 per cent. in 1934 and 13 per cent. in 1935, good and poor years respectively from the growers' point of view. It is thus apparent that there is scope for a large increase in home production.

N.S.P.C.C. Annual Report

The annual report (1936–7) of the National Society for the Prevention of Cruelty to Children records a slight increase in the number of cases reported to the society during the year. This increase was largely due to cases in which the parents of the children concerned came voluntarily to ask the advice of the society with regard to their domestic problems. The report comments on the tendency of the general public to express dissatisfaction with the adequacy of the sentences imposed in cases prosecuted by the society. It is pointed out, however, that such penalties as heavy fines or terms of imprisonment, unless accompanied by the transfer of the legal custody of the children, bear as heavily upon the children as upon the parents. Also it must be remembered that the really severe part of the sentence is contained in a decision to deprive parents of the custody of their children. The report states that the society is deeply sensible of the care and thought given to these cases by the justices, and of the wisdom and helpfulness of their decisions. An unsatisfactory feature of the year's work is the decrease in the number of cases reported by the general public. Many of the worst cases could have been brought to the society's notice by neighbours at an earlier date, a course of action which would have shortened the unnecessary sufferings of a large number of children. During the year the medical department dealt with 2,573 cases, of which 463 required orthopaedic treatment for various deformities.

SCOTLAND

Royal College of Physicians of Edinburgh

The annual report (1936) of the Laboratory of the Royal College of Physicians of Edinburgh records the publication of nine papers during the year under review. Work on the toxic effects on animals of substances in common industrial use has been carried out in collaboration with Dr. T. Ferguson and Dr. B. Wylam of the Department of Health for Scotland. The results of a study of the effect of trichlorethylene on rats appear to show that this substance exerts a deleterious effect at least upon the liver and the bone marrow. Whether this effect upon rats is of significance for man depends entirely upon the concentration of the substance in the air breathed by those exposed to it. It is hoped, following improvements envisaged in the special apparatus employed, to discover an answer to the question whether trichlorethylene and other substances may effect the health of workers. Mention is also made of epidemiological statistical researches, a review of the results of anti-rabic treatment,

a study of the pathology of the breast, and an investigation of calcium deposits. The report records with regret the death of Mr. T. D. Hamilton, who was associated with the laboratory for many years. Mr. Hamilton's work was chiefly concerned with section technique, the morphological aspects of cancer, and the establishment of standards in blood examination.

New Glasgow Professor

Professor George Barger, who at present occupies the chair of chemistry in relation to medicine at Edinburgh University, has been appointed regius professor of chemistry at the University of Glasgow in place of Professor George Gerald Henderson, who has resigned as from September 30. Professor Barger, who was born in 1878, was a Fellow of King's College, Cambridge, from 1904 to 1910, and head of the chemical department, Goldsmith's College, from 1909 to 1913. In the latter year he became professor of chemistry at the Royal Holloway College, University of London, and a year later chemist on the staff of the Medical Research Committee. In 1919 he was appointed to the newly instituted chair of chemistry in relation to medicine at the University of Edinburgh. Professor Barger has carried out much research in organic chemistry, and is the author of several books dealing with this subject, including one on *Organic Chemistry for Medical Students*, published in 1932, and a work on *Ergot and Ergotism*. In 1928 he delivered the course of Baker Lectures at Cornell University, and of Dohme Lectures at the Johns Hopkins University in the United States. He was awarded the Hanbury medal of the Pharmaceutical Society in 1934 and the Longstaff medal of the Chemical Society in 1936.

IRELAND

Health of Belfast

Four principal subjects are dealt with in the report on the health of the county borough of Belfast for 1936 by Dr. C. S. Thomson, medical superintendent officer of health. An account is first given of the work of mosquito control in the three prolific breeding grounds in the area. Dr. Thomson says that mosquitos are not only a serious annoyance but a danger to health in view of the possibility of sepsis following upon bites. The salt marsh mosquito (*Aedes detritus*) is chiefly responsible. A staff of five men is kept continually at work oiling the breeding places with waste motor oil collected from city garages. Another new health enterprise is immunization against diphtheria, a work which started in October last, but has been so vigorously undertaken that within little more than six months 4,215 children completed the immunization course. The annual notifications of diphtheria in Belfast in the last seven years have varied from some 400 to 1,200, and the deaths from thirteen to fifty-five. Dr. Thomson looks forward to an immunization rate during the next five years of about 27,000 a year. On the subject of housing he points out that Belfast is comparatively a modern city, without the large areas of wretched housing to be seen elsewhere: nevertheless there are some 2,000 houses which should be demolished, and it is hoped to accomplish this clearance by degrees. An encouraging report is given on maternity and child welfare. In the hospitals and municipal clinics 5,165 first ante-natal examinations were made, and there were 17,885 subsequent visits, plus an unascertained amount of private ante-natal supervision by medical men. The birth rate was 21.2 per 1,000, and the death rate 14.2, the one slightly below and the other slightly above the average of the last ten years. The infant mortality rate was 101 per 1,000 births.

INDIA

Research at the Calcutta School of Tropical Medicine

In 1936 the research investigations at the Calcutta School of Tropical Medicine were on malaria transmission, indigenous drugs, drug addiction, medical mycology, helminthology, anaemia of women, kala-azar, cholera, and special studies of epidemic dropsy, leprosy, and filaria. A case of agranulocytosis was discovered in Calcutta, one of the first to be reported in India. The patient had been in the habit of taking an amydopyrine derivative, and succumbed before nucleotide therapy could be tried. In the annual report of this institution for 1936 it is mentioned that the bacteriophage-therapy investigation as regards cholera has now been completed, 1,748 patients having been watched. Analysis of the results indicated that this procedure in cholera has a definite therapeutic value. Attempts are in progress to determine the mode of action of quinine and atebrin on *Plasmodium knowlesi*. It has been shown that a 1 in 50,000 atebrin solution can destroy the parasites even when the infection is very heavy. The smears of blood kept in contact with atebrin for twenty-four hours showed degenerative changes in them, and a susceptible host (*Silenus rhesus*) inoculated with this mixture was not infected. But a much stronger solution of quinine (1 in 10,000) failed to kill the parasites. In the pharmacological department work was continued on the pharmacology of snake venoms and camphor compounds. chemotherapeutic studies were performed with regard to the action of atebrin in monkey malaria and the atebrin–plasmoquine combination in human malaria, and new and efficient methods were elaborated for the estimation of atebrin and lecithin in the blood. A number of inorganic compounds used in Hindu medicine were investigated, as well as many medicinal plants. The data on hemp drug addictions are now being analysed. Important research work has been conducted on the distribution of blood groups in the Indian Army, and a technique has been evolved for the determination of blood groups from stains. A clinical trial of a special vaccine prepared from virulent cultures of two types of pneumococcus isolated in Assam gave encouraging results clinically; in a series of twenty-three cases there was only one death. It has been shown also that there is a type of severe macrocytic anaemia prevalent on the east side of India, which, unlike the microcytic anaemia, can be cured by the giving of a rich well-balanced diet. The previous work of Professor L. E. Napier had shown that the microcytic anaemia common among coolies was uninfluenced by the introduction of a good diet, and was cured only when iron was given. In collaboration with Dr. Wilson an investigation is being continued to ascertain which particular dietetic factor is responsible for improvement in the macrocytic cases. Leprolin and diathermy have been tried for the relief of neuritis in leprosy, as well as the injection of colloidal copper, cobra venoms, and hydnocarpus preparations around the nerves and into the affected areas. A careful study of the tuberculoid type of leprosy has been made, and its recognition and differentiation from ordinary leprous infiltration in the skin has been found to be very important from the point of view of prognosis. No evidence has yet been obtained of the growth of lepra bacilli in tissue cultures. It has been shown that there are patients suffering from cholera and passing typical rice-water stools in whom, despite very extensive research, only non-agglutinable vibrios can be found. In diabetic subjects it has been found that the degree of hypercholesteraemia is a much more satisfactory index of the severity of the disease than is any one of the other single factors, including hyperglycaemia. It was only cases with marked hypercholesteraemia that had complications such as arteriosclerosis and retinitis. Sexual immaturity seemed to be very closely associated with diabetes.

Madras Government Ophthalmic Hospital

During 1936 treatment was given to 31,609 out-patients at the Madras Ophthalmic Hospital and there were 4,391 new in-patients. The surplus sick were as usual accommodated in the verandas. Twenty-four beds are available for European and Anglo-Indian patients, and 146 for Indians, so that the accommodation is at times very strained. In the twelve months under review 2,954 patients were discharged as cured and 1,197 as relieved; there were eight deaths. The commonest pathological conditions were senile cataract; chronic, angular, and acute conjunctivitis; glaucoma; errors of refraction; corneal opacities and ulcerations; pterygium; diseases of the eyelids; and presbyopia. The large range of eye disorders dealt with renders this institution a particularly valuable centre for the training of medical students and postgraduates, of whom there were 231 and twenty-three respectively. The daily average attendance of patients was rather smaller than in 1935, and there were consequent reductions in the expenditure on drugs and dietaries. Establishment costs increased slightly but less was spent on the buildings. The number of surgical operations performed in 1936 was 8,162. Lens extractions were common, and other procedures included operations on the lachrymal sac and nasal duct and on the eyeball and another frequent procedure, as was also the treatment of prolapsed iris. Radium treatment was given for certain ophthalmic new growths with considerable success.

FRANCE

[FROM OUR CORRESPONDENT IN PARIS]

International Medical Meetings

The summer of 1937 stands out as remarkable for the number and importance of the international medical meetings held in Paris in connexion with the Exhibition. There must have been scores of such meetings, and some of the doctors who attempted to attend several may well be excused if the orgy they indulged in has left them a trifle confused although enlightened. Some overlapping was, of course, inevitable, but on the whole the organization of these meetings has given satisfaction and also the impression that the Gallic taste for orderliness is as keen as ever. At the cost of making what may seem invidious distinctions, reference will be made here to only a few of these meetings.

Under the presidency of Professor Laignel-Lavastine, the first International Congress of Neo-Hippocratic Medicine enjoyed the patronage of the Paris faculty of medicine and was attended by many of the most distinguished members of the medical profession, the President of the Academy of Sciences, the President of the Academy of Medicine, the doyens of the faculties of medicine and pharmacy of Paris, and many others. The sixteenth annual International Neurological Congress was opened on July 8 under the auspices of the faculty of medicine and the presidency of Professor Barré of Strasbourg. Altogether nine main reports were presented whose principal theme was pain as a neurological problem.

QUACKERY AND PUBLIC HEALTH

Les Journées Internationales de la Santé Publique occupied half a score of days and embraced a wide range of subjects grouped under ten different sections. Special mention may here be made of the sixth section, which dealt with the merchant service and to which the League of Red Cross Societies gave its patronage on account of its interest in the health of the merchant seaman. A most interesting communication was made to this section by Dr. Bernard of Belgium, who discussed the problem of wireless communications between doctors on shore and ships not carrying a doctor. These Journées included a discussion on quackery, which was held on July 7 under the auspices of the International Committee for Combating Charlatanism. Many of the speakers followed conventional lines, but there was a touch of both unconventionality and audacity in the suggestion of one speaker that the out-and-out quack might be less of a danger to the community than the fully qualified doctor with the "soul of a charlatan." When such a man "covered" unqualified medical practice the public was sore put to it to escape fleecing. Another speaker advocated the complete prohibition of written and wireless publicity in favour of quack treatment, this prohibition to be extended to the cinema and luminous advertisements. Publications not exclusively devoted to medicine or pharmacy were not to advertise prophylactic or therapeutic devices, and touting through the mail was to be forbidden. It was also proposed that a quackery commission should be appointed, and that on it should be represented the Conseil Supérieur d'Hygiène and other important bodies. Yet another suggestion concerned the supervision and regulation of titles and claims to special knowledge of certain subjects, the term "specialist" to be earned, not just self-bestowed. The most reassuring feature of this discussion was the tribute paid to the sickness insurance scheme—Assurances Sociales.

From July 19 to 25, and in the presence of a distinguished gathering, the International Congress of Mental Hygiene was held at the Centre Marcellin-Berthelot. The president was Dr. Toulouse, and a well-known figure was Mr. Clifford Beers, who has done so much to promote the cause of mental hygiene throughout the world. The fact that the President of the Republic was represented at this congress was only one of many signs indicative of its importance.

The New Minister of Public Health

M. Henri Sellier, Minister of Public Health in the Blum Cabinet, has been succeeded by M. Marc Rucart, whose recent public utterances have inevitably reflected the sombre condition of French finance at the present time. Sellier may have been an expensive Minister of Public Health, but what a driving and enterprising force he proved himself to be! It is to be feared that in many fields he may have put his hand to the plough in vain because the Blum Government had not taken Micawber's law of balanced accounts sufficiently to heart. It is to be hoped, however, that the reforms connected with prostitution and venereal disease will yet materialize, at any rate in so far as they do not drain the public purse too openly. Rucart's future achievements must be judged with a leniency inspired by knowledge of the limited financial means at his disposal.

G. S. Hall (*J. Neurol. Psychopath.*, January, 1937, p. 262) points out that chronic subdural haematoma is not a rare clinical entity, and should be distinguished from the acute type. He records four cases which he encountered in one year. Increased intracranial pressure did not occur in all the cases, but it was found that the symptoms depended on the degree of increase in the intracranial pressure present. This in turn depended on the age of the patient, the younger patients having the highest pressure. A review of the literature supports the view that the clinical picture of the condition and the occurrence of raised intracranial pressure are both determined by the age period in which the lesion develops. In infancy the pressure is so high that the condition mimics "idiopathic" hydrocephalus. In middle life the picture is one of increased intracranial pressure, while in later life the condition is difficult to recognize, as the pressure is not raised at all.

Correspondence

The Radiology of Megacolon

SIR,—Dr. John R. Wylie in his letter to the *Journal* of August 21 states that the normal variations in tone of the alimentary tract have been frequently misunderstood by the radiologist. This is doubtless a result of insufficient study of Sherrington's fundamental work on the postural tone and postural length of involuntary muscle, without which it is impossible to interpret the significance of the considerable changes which occur in the size, shape, and position of the stomach and colon in every individual in the course of a single day. There is, however, no excuse for ignorance on the subject since the publication of Dr. A. E. Barclay's *Digestive Tract*. In his criticism of my views on the interpretation of the information given by an opaque enema in cases of megacolon Dr. Wylie himself shows a want of familiarity with Sherrington's work.

The tone of the stomach can be judged from the level of the upper limit of its contents when viewed at *x*-ray examination after an opaque meal. The size of the latter is immaterial, as the tone varies with the bulk in such a way that the intragastric pressure remains constant. It is, however, customary to give a comparatively small meal, as most people would find it difficult to take a large quantity of the opaque mixture. If the tone of the stomach were judged in a manner corresponding with that advised by Dr. Wylie for the colon, the patient would have his stomach filled through a tube with a thin suspension of barium under a constant (and presumably low) pressure until he felt full enough to vomit. This would, however, show nothing more than the distensibility and maximum capacity of the stomach, which have nothing whatever to do with its tone.

The postural tone of the colon, like that of all other hollow viscera, adapts itself to the volume of its contents, with the result that the pressure within it remains approximately constant. The diameter of different parts of the colon and its total length show great variations during the day. Thus, in the early morning the pelvic colon is full and its postural tone is low, so that its length and diameter and consequently its capacity may be sufficiently great to hold all its contents. But immediately after defaecation the pelvic colon is empty; its postural tone is then maximal and its lumen entirely obliterated. The appearance of the pelvic colon after a barium enema given as recommended by Dr. Wylie shows its size with minimal postural tone if time is allowed for complete relaxation to occur. But to say that it gives a good estimate of bowel tone is quite meaningless, as the tone depends on the volume of its contents, varying between a maximum when it is empty, an average minimum when it is full just before defaecation, and an extreme minimum, corresponding with the greatest distension it has ever experienced, when it is fully relaxed after an opaque enema. Consequently, in both children and adults with megacolon, an opaque enema always shows a greatly dilated pelvic colon, even years after complete recovery, whether the result of medical treatment or sympathectomy. An opaque enema is therefore valueless as an estimate of the success of treatment. The appearance of the abdomen is the best guide in children, but an opaque meal and the sigmoidoscope can also give valuable information. The latter show that the postural tone of the individual muscle fibres of the circular and longitudinal muscle coats, and with them the diameter and length respectively of the pelvic colon, may have returned to normal, even when an opaque enema shows that the colon is still capable of being greatly distended if fluid is slowly run into it from below, a condition which bears no relation to anything occurring under normal conditions of life.

The radiological examination of the renal pelvis gives a good illustration of the difference between tone and distensibility. Intravenous pyelography shows the size of the pelvis under natural conditions, the tone of its musculature and therefore its size being adapted to the amount of urine secreted at the moment. On the other hand, retrograde pyelography shows its size when distended to a degree sufficient to cause slight discomfort. In early cases of intermittent hydronephrosis intravenous pyelography reveals a pelvis of normal size, but the retrograde pyelogram reveals an enlargement corresponding with the size of the pelvis during an attack—that is, it affords a measure of its distensibility, which depends upon the maximal size it has hitherto attained and not its average size under normal conditions between attacks. The intravenous pyelogram corresponds with the appearance of the colon after an opaque meal, the retrograde pyelogram with that after an opaque enema.—I am, etc.,

ARTHUR F. HURST.

New Lodge Clinic, Windsor Forest, Sept. 3.

Cataract Extraction

SIR,—Mr. Basil Graves gives in his interesting paper in the *Journal* of August 14 (p. 319) a description of his technique of cataract extraction during narcosis. In preference to his rather complicated method I adopt the simplest possible (*Arch. Ophthal.*, Chicago, 1934, 2, 102). Briefly, this consists of the instillation of five drops of cocaine thirty minutes before operation; suture fixation; retrobulbar injection of novocain-suprarenin; lobular incision with a conjunctival flap; iridectomy; and finally intracapsular extraction by the direct method without tumbling the lens, using Arruga forceps. Loss of the vitreous has followed in only 2 per cent. of cases, and an unfavourable result in only 0.5 per cent. "Expulsive haemorrhages" in the last ten years have occurred in only four instances out of 5,000 cataract extractions.—I am, etc.,

Budapest, Aug. 19. EMILE DE GRÓSZ.

SIR,—I have read with much interest Mr. Basil Graves's account of his method of narcosis for eye operations—in particular cataract extraction. A certain amount of experience in eye work, from the point of view of a civil surgeon in India, enables me to appreciate the great advantage of something approaching general anaesthesia in operating for cataract if the co-operation of the patient can be dispensed with, as in Mr. Graves's method. Unconsciousness of the patient is a gain not only to him, but also to the surgeon. I know from experience that the tendency to tremor in fine work of this description is much increased by the knowledge that the patient is nervous, and perhaps even suffering some pain.

My interest in the subject is heightened by the fact that Mr. Graves operated on me for cataract last year, and again, on the other eye, nearly three months ago. On the former occasion, nembutal being used, I was conscious, but went to sleep immediately after the operation, and slept soundly throughout the night. During the second

operation, following the administration of omnopon and rectal paraldehyde, I was completely unconscious, and I slept as before without any intermission until the following morning. In both cases the operation was at about 5 p.m. The ultimate result in both eyes leaves nothing to be desired. It may be said, admittedly, that I am not an unprejudiced observer. I am a very grateful patient. But my experience of what seems to me a most useful revolution in the operative treatment of cataract may be of interest.—I am, etc.,

Bournemouth, Aug. 25. A. HOOTON.

The Place of Pharmacology in the Medical Curriculum

SIR,—Now that most of the medical institutions, both in England and India, will soon adopt the revised medical curriculum, and criticisms from different sources have been recorded, may I be permitted to make a few observations.

In none of the criticisms which appeared was the subject of pharmacology discussed. No one can deny that to be a successful practitioner, or even a specialist, one must know the subject of pharmacology and its practical application in disease. About a quarter of a century ago pharmacology was taught with therapeutics, and the names of men like Sir Lauder Brunton, Mitchell Bruce, Sir Thomas Fraser, and Professor Ralph Stockman naturally come to mind. Fortunately, Professor Stockman is still with us. These professors had clinical beds, and were thus able to impress on the students the practical application of the knowledge of pharmacology in disease. As time went on the science of pharmacology developed, and it was thought that the subject should be taught with experiments so that the student would be able to visualize the action of drugs on animals. This no doubt made the teaching of pharmacology more interesting, and it was separated from therapeutics, which was taught as a detached subject. The result was that while a student, or for the matter of that a junior practitioner, was conversant with the pharmacological action of a drug, he was hopelessly ignorant of the practical application of that knowledge in therapeutics. While more attention was paid to the teaching of pharmacology as a scientific subject pure and simple, the teaching of therapeutics was neglected, and no proper attention was given to the teaching of materia medica proper—that is, prescription writing, incompatibility, etc. No one will question the value of experimental work, but pharmacology is not all experiments, and it has to be conceded that the primary object of teaching the subject is to enable the student to appreciate the rational basis of therapeutics, and the best way to estimate the practical value of this form of teaching is to see how far we have been able to attain the objective we have in mind. To teach the different subjects in separate watertight compartments is a great mistake, and the modern teaching entails that each of the basic subjects should be taught as an applied subject.

Having taught pharmacology for over twenty years, and also having had the opportunity of coming into contact with students in different parts of India, I am convinced that to teach the subject as we have been doing will lead us nowhere, and that it is time we faced facts and rearranged the method of teaching on the basis of our past experience. It will be interesting to hear the experience of other teachers on the subject and to have their constructive suggestions. To my mind the subject of pharmacology should be taught in the clinical period, and therapeutics should be closely co-ordinated with it. Moreover, pharmacology and therapeutics should be taught by the same teacher, who should be in charge of clinical beds.—I am, etc.,

B. N. GHOSH, F.R.F.P.S.Glas.,
Calcutta, Aug. 23. Professor of Pharmacology, Carmichael Medical College.

The Teaching of Medicine

SIR,—Much of Sir David Wilkie's article in your Educational Number (September 4, p. 439) is as pertinent to other branches of teaching as to his own, and his views invite more than our tacit acceptance. To teacher and student alike the implication of these words is a call: "Our object is to educate rather than to instruct. . . . The greater the co-ordination and harmony . . . the more complete and generous will be the education." Co-ordination and harmony are conspicuously lacking in the world to-day, and each of us must make his choice between a course of discord and one along which harmony can be restored to our lives and those of our fellows. The latter can be attained at the cost of a complete revolution in oneself.

It has come home to me lately that my own teaching has often been dishonest, and the sequel to such dishonesty is interesting. A few evenings ago at my own fireside I invited from a recent graduate of my own school his views on the clinical side of medical teaching. What I learned is not difficult to guess; when I had taken considerable trouble over the preparation of a clinic the student derived considerable benefit from it, but when conflicting interests or self-assurance had prompted me to teach on a patient whom I had not made the subject of careful study, however simple the condition—perhaps a straightforward valvular heart disease—the student's time and my own were largely wasted. I discussed with my friend some of the difficulties that students of medicine have, and there can be little doubt that one upsetting feature of teaching is the disharmony of view, it may be on nomenclature, on classification, or on the significance of a particular sign, on anything in fact that the student encounters in different teachers. When I say to myself "I do not agree with So-and-so's opinions or methods" I am putting a stumbling-block in the student's way, and there may be no obstacle to my acceptance of So-and-so but my own self.

My friend and I also shared a conviction that there is too wide a gulf between the teacher and the student. If, by aloofness which I hope will call forth respect, or by witticism at a student's expense, or by sarcasm, which I think is gentle but which he knows to be cruel, I help to establish and maintain that gulf, I cannot hope to send that man into the world at the end of his course equipped to build bridges across the hundred and one gulfs he will encounter between himself and his fellows. If I am teaching students and there is disharmony in my own life, their education, so far as I am responsible for it, will assuredly be neither complete nor generous. I cannot establish harmony between myself and my fellow, whether student or teacher, by condescension or patronage, but if he and I will allow our working day to be permeated by a spirit of fellow-discipleship of the Highest Teacher of all under His guidance we can play our part in helping our profession to take its appointed place in the rehabilitation of this tottering world.—I am, etc.,

Dundee, Sept. 5. JAMES M. STALKER.

Medical Records

SIR,—It would surely be of the utmost value to everybody concerned if a central record office could be established in London to pool information relating to investigations carried out upon patients in hospitals, operations performed, etc. At the present time a patient will often pass through an elaborate series of investigations in one hospital, and then in the course of months, or it may be two or three years later, will go to another hospital, where a similar series of investigations are carried out. Similarly, a patient may have a laparotomy performed for diagnostic purposes, and at a future date, as a result of a recurrence of the symptoms, may seek advice at another hospital where, lacking precise information as to the results of the former investigation, another laparotomy is performed. This is particularly true of the patient who has what may be termed a neurotic constitution with a tendency to autonomic and endocrine imbalance, which results in various forms of physical dysfunction with symptoms the exact significance of which it is extremely difficult to assess. Such patients have a tendency to wander from doctor to doctor and from hospital to hospital. It is obviously inadvisable to give the patient a written account of the results of investigations, operative procedures, and the like, as this in itself might constitute a basis for the development of a hypochondriacal outlook in a predisposed person, and would often cause unnecessary suffering.

All records, therefore, are at present buried deep in the files of the individual hospital. It is true that in theory at least it is possible to obtain some information by communicating with the registrar, but this is seldom complete, and when it has to be collected from various sources involves a delay which often renders it of little value. The existence of a central record office where a brief report of the investigations, surgical procedures, diagnosis, and prognosis could be filed and obtained by any general practitioner or any other hospital would be a labour-saving device of the first order. It would, moreover, form an invaluable body of information available for research purposes. The expense of setting up and maintaining such a central co-ordinating bureau would admittedly be considerable, but the saving to the hospitals using it would also be on a vast scale both *in time and money*, and the advantage to the public and to medical science generally would be incalculable. It could be financed partly by means of contributions from the hospitals using it, by payments made for information given in respect of individual patients, by trust and charitable funds, and possibly by Government and local authority grants.—I am, etc.,

London, W.1, Aug. 25. DORIS M. ODLUM.

Sulphanilamide in the Treatment of Gonococcal Infections

SIR,—When this remarkable drug, sulphanilamide, was discovered to have a specific action against infections due to the haemolytic streptococcus, the meningococcus, and some other bacteria, it was hoped that it might be effective against the gonococcus. As soon as it was available many authorities in England, Ireland, and on the Continent, including the original makers of the drug, tried its action on gonococcal infections and reluctantly concluded that it was unsatisfactory.

At the instigation of the Therapeutic Trials Committee of the Medical Research Council I tested two series of patients suffering from acute gonococcal urethritis: four cases with prontosil album, the original German preparation, and fifteen with a drug of British manufacture. The results were distinctly disappointing, and other venereologists in this country had similar experiences. More recently Dees and Colston (*J. Amer. med. Ass.*, May 29, 1937) refer to the use of sulphanilamide in gonococcal infections. They concluded that the drug will prove of great value in this disease. The prompt response to treatment in the majority of their cases (nineteen in all), the smooth clinical course, the fact that no complications occurred and that the infection had not progressed, together with the reduction in hospital expenses, impressed them profoundly. The possibilities of sulphanilamide in treating gonococcal infections also formed the subject of discussion at the recent meetings of the American Medical Association at Atlantic City, the American Neisserian Society, also at Atlantic City, and at the American Academy of Pediatrics in New York City. At these conferences many physicians expressed their opinion that the drug could be regarded almost as specific in gonorrhoea as it is in the treatment of haemolytic streptococcal infections.

As a smaller initial dose was given during my previous trials than that used by Dees and Colston, tests were repeated on a third series of twenty acute cases. The treatment outlined by these workers was followed exactly —that is, four divided doses a day, 4.8 grammes of sulphanilamide daily for two days, 3.6 grammes daily for three days, and then 2.4 grammes daily for from four to eight days. No other treatment, either local or general, was used, and, as before, the results were unsatisfactory. To summarize, my experience with sulphanilamide administered orally in the treatment of acute cases of gonorrhoea is that it is ineffective. The drug does not appear to act satisfactorily in combating the gonococcus, however good it may be in some other infections.—I am, etc.,

London, W.1, Aug. 25. T. ANWYL-DAVIES.

Treatment of Giant-cell Tumour of Bone

SIR,—I am grateful for Mr. R. C. Elmslie's letter (*Journal*, August 28, p. 431) on giant-cell tumours of bone, with much of which I am in agreement. There are, however, some points on which more precise information is required, and several inaccuracies must be corrected.

1. That a tumour of bone can only be diagnosed with certainty by a biopsy is self-evident. The practical point, however, is that when a first-class radiologist says that a tumour of bone is a giant-cell tumour the probability that he is correct is such that treatment based on his opinion is completely justified. At the Presbyterian Hospital a mistaken diagnosis is made in about 5 per cent. of cases. Will Mr. Elmslie, or the radiologists, tell us what percentage error they expect? Many do not regard the occasional error as a serious mistake, for the surgical results in such cases are so dismal.

2. It is pleasing to learn that there was agreement that a biopsy should be free and the sections made at leisure. As a pathologist I am acutely conscious that there is not general agreement on this point anywhere, though I believe it to be correct. Among the New York surgeons mentioned Dr. Auchincloss definitely disagrees. It is easy to name other leading surgeons here and abroad who also disagree. The greatest danger of a frozen section is that a diagnosis may be made which is not justified by the preparation, but that does not alter the fact that in many cases the diagnosis from the quick section is quite reliable.

3. I do not think anybody disputes that a giant-cell tumour can be cured by curetting, and it is pleasing that there is no dispute that they can equally be cured by radiotherapy. However, I will indeed be most surprised if there are many who will agree with Mr. Elmslie that surgery is safe and simple while radiotherapy is dangerous. Surely the reverse is true,

and is the reason why most patients will be disappointed that "most surgeons will prefer to keep to the knife." I will refuse to believe that there are competent radiologists who forget that there are such things as skin, muscle, etc., but it is delightful to learn that they can forget that women have genital organs.

Mr. Elmslie completely missed the point of the case I quoted. An accurate diagnosis was made from the original *x*-ray photographs and was acted on correctly. Quite a number, including James Ewing, said that an ideal result would have followed. The lesson learned was not that radiotherapy is dangerous, but that the radiographic appearance of giant-cell tumours undergoing treatment needs to be more generally understood. Radiotherapy is in its infancy compared with surgery, and these lessons have to be learned. Nevertheless, the elaborate follow-up system used by the Americans (which we so rightly admire) does seem to show that except for special cases radiotherapy is the treatment of election. Curetting is not condemned, but it has been observed that it is dangerous to use both local surgery and radiotherapy. Because it is difficult to explain this observation we must not doubt its truth; I have seen it convert a benign into a malignant giant-cell tumour myself. Dr. Haagensen is emphatic about the danger, and the observations were on cases which had a biopsy at the start—and a necropsy at the end. This danger is not an argument against radiotherapy at all. It is an argument for competent radiologists, and if one is not available or is not reasonably sure that the lesion is a giant-cell tumour then the surgeon should rely on himself alone for treatment. It should be needless to add that I did not say that merely cutting into an innocent tumour can render it malignant.

It is evident that there will be two schools of thought on this subject for some time. I have no doubt, however, how I would prefer to be treated myself.—I am, etc.,

Derby, Aug. 28. G. R. OSBORN.

SIR,—Had the summary of my remarks at the discussion which I submitted (on the forms provided) on July 26 been published or consulted in making up the report of the proceedings for the *Journal* of August 7 it would not have been necessary for me to reply to Mr. Elmslie's letter, in which he states that there was general agreement upon three points, for two of these are in direct opposition to the experiences which I there related—namely, (1) that a tumour of bone could only be diagnosed with certainty by means of a biopsy; (2) that an osteoclastoma is capable of cure by the simple and safe surgical procedure of curetting. To show how little agreement existed between us over these points I should like to criticize the report which was printed in the *Journal* of August 7, and for this purpose shall indicate the report in italics and follow each statement with my comments.

1. "*The clinician was becoming increasingly anxious to pass the responsibility of diagnosis on to the radiologist.*" What I said was that, while in some cases the diagnosis on radiographic evidence was definite and could be acted upon by adopting prompt radical surgical procedures, unfortunately there were cases in which the clinical, histological, and radiographic evidence was insufficiently convincing to the surgeon to warrant mutilating surgery, and owing to the poor results of the latter in bone sarcomata the clinician was more and more seeking the refuge of radiotherapy—at any rate until the nature of the lesion had revealed itself. It is well known that for some months following radiotherapy the radiographic appearances of an osteoclastoma suggest that the tumour is extending, but subsequent radiographs show increased consolidation. In spite of this apparent healing I stated that in my experience local resection of a simple tumour was preferable to either *x*-radiation or curetting: the former may leave the patient with destructive effects and pains more serious than the bone tumour, while even after thorough curetting malignant metaplasia of remaining tumour cells may occur. I have published an account (see *Proc. roy. Soc. Med.*, 1937, **30**, 9, and *Brit. J. Rad.*, 1937, **10**, N.S. No. 111) of such sequelae fifteen years after curetting; it has followed curetting of so-called localized fibrocystic disease; we have no proof that similar metaplasia will not occur if the only treatment is radiation. *X*-radiation is probably justifiable only in the case of inoperable tumours, and even with these the results are not very hopeful. The best American results in bone sarcomata were obtained by amputation or resection followed by the administration of Coley's fluid.

Regarding biopsy, I stated that it was in some cases dangerous and misleading, for following trauma, either accidental or surgical, malignant bone tumours appeared to show more rapid growth and metastases were to be detected soon after. In support of the more serious charge of "misleading" I exhibited the radiographs of a number of cases in which the radiographs indicated innocence, but the histology malignancy, and others in which the radiographs indicated malignancy whereas the histology favoured innocence and the subsequent histories had proved the radiographic evidence to be the correct.

2. "*The radiodiagnostic test was not dangerous unless the surgeon refused to intervene when radiation treatment failed.*" In this case the reporter's interpretation is absolutely wrong. When the radiodiagnostic test is applied to an endothelioma of bone (Ewing's tumour) the tumour in some cases responds and the bone may even take on the radiographic characters of normality. Such a response is regarded as evidence that the lesion is a sarcoma and calls for drastic surgical measures in spite of the apparently good response, which, alas, is only temporary and not curative. It can therefore hardly be said that the radiation has failed, or even succeeded, but if the apparent success (not failure) checks or delays surgical intervention the test introduces the element of danger. Surgery is not undertaken for bone sarcomata which have been undergoing frank radiation therapy (not a short test) and failed to respond, except for the temporary relief of pain and removal of a fungating mass: therefore failure to adopt surgical measures when radiation has failed cannot be regarded as dangerous.

Because I was able to show that in some cases either the clinical or the histological or the radiographic examination alone supplied the essential evidence, and that evidence from one or the other of these sources might be inconclusive or misleading, I pleaded for a more intimate co-operation of surgeon, pathologist, and radiologist in all cases.

—I am, etc.,

Birmingham, Aug. 30. JAMES F. BRAILSFORD.

*** It must be pointed out that Dr. Brailsford did not give the summary of his remarks to the reporter at the Meeting, as requested in the directions in the handbook of the Meeting. In the account given in the *Journal* of August 7 (p. 285) of Dr. Brailsford's remarks six of the nine points raised by him were correctly reported, two were records of the impressions of the reporter, and the third (No. 2 in Dr. Brailsford's letter) was apparently misleading.—ED., *B.M.J.*

Bilateral Artificial Pneumothorax

SIR,—While disagreeing with much that is said in Dr. Crocket's article in the *Journal* of August 7 (p. 261), particularly with the technique applied, I feel that he has done good service in drawing attention to bilateral pneumothorax. But as he has not given any figures perhaps those of bilateral pneumothorax undertaken at the Cheshire Joint Sanatorium might be of interest. The classification of bilateral artificial pneumothorax I adopted is as follows:

PRIMARY BILATERAL

(*a*) *Immediate.*—Cases with bilateral disease at the initial examination and in which a double artificial pneumothorax

(A.P.) is at once prescribed, both sides being collapsed as soon as possible. If one side cannot be collapsed the case is transferred to Choice 3 of unilateral A.P.

(*b*) *Delayed.*—Cases similar to group (*a*) but in which only the more severe side is collapsed at once and expectant or other treatment adopted for the contralateral lung. Later this lung is unaltered, or worse, and therefore collapsed, thus giving a bilateral A.P.

Primary Bilateral

Year of Induction	No. of Cases	Years since Induction	Alive		Alive, March, 1937	
			No.	Per cent.	No.	Per cent.
1930–4 inclusive	92	2	62	67.39	54	58.7
1930–3 „	65	2	41	63	33	50.76
		3	37	57		
1930–2 „	32	2	17	53	11	34.37
		3	15	47		
		4	12	37.5		

SECONDARY BILATERAL

A group of cases initially considered as a good selection for unilateral A.P., but later an acute spread in the contralateral lung occurs and this side is collapsed concurrently with the other.

Secondary Bilateral

Year of Induction	No. of Cases	Years since Induction	Alive		Alive, March, 1937	
			No.	Per cent.	No.	Per cent.
1929–34 inclusive	33	2	23	70	21	63.63
1929–33 „	26	2	16	61.54	14	53.84

CONTRALATERAL ARTIFICIAL PNEUMOTHORAX (A FREAK)

Artificial pneumothorax on healthy side with a view to controlling the diseased side.

—I am, etc.,

Cheshire Joint Sanatorium, Market Drayton, Aug. 30. PETER W. EDWARDS.

Ambulatory Artificial Pneumothorax

SIR,—We read with great interest the excellent article by Dr. James Crocket on artificial pneumothorax treatment in the *Journal* of August 7 (p. 261). We propose to comply with the implied invitation in the section on ambulatory artificial pneumothorax, and regret we have not been able to do so earlier.

During the past five years we have found it necessary to induce ambulatory artificial pneumothorax in thirty-six cases. In the majority of these the induction was carried out at the dispensary and a few in the patients' homes. The patients were conveyed by car or ambulance and screened before and after induction. They rested on a couch for two or three hours, as it was felt that any complication due to the induction would have manifested itself during this period. Nineteen of these patients were subsequently admitted to hospital after an average waiting period of three months. It is our opinion that the time of institutional treatment was definitely shortened by the artificial pneumothorax, and in the majority of these cases there is every probability that, had the treatment not been started at the dispensary, the disease would have progressed so that unilateral artificial pneumothorax might have been impossible. The remaining patients were treated entirely at the dispensary, and among these have been some of our most successful cases. One, a male aged 24, has gained over three stones in weight during his year's treatment, and radiologically there is marked clearing of the disease.

It will be a matter of interest to Dr. Crocket to know that we have also induced five cases of simultaneous bilateral artificial pneumothorax. One, we hope, is proceeding to ultimate cure. Having lost a stone the patient regained it after the second induction, and *x*-ray examination now shows little evidence of active disease. Two other patients, females aged 19 and 20, are doing very satisfactorily both clinically and radiologically, and in spite of their age group we are very optimistic regarding the prognosis; one of these cases was complicated by bilateral effusion. For differing reasons none of these three cases has received hospital treatment since the second induction. The other two patients died. One was a girl of 15, who, however, gained one stone after the second induction. The other, a young woman, suffered an extension of the disease to the opposite side following the birth of a child; she also made some initial progress following the second induction and gained 3 lb.

Full notes, films, and diagrams of screenings of all the cases are available, and we hope after the lapse of the necessary time to publish our results.—We are, etc.,

Chronic Disseminated Tuberculosis

SIR,—The book by Clifford Hoyle and Michael Vasey reviewed in the *Journal* of August 28 (p. 421), the paper by R. H. Fish in the *Archives of Diseases in Childhood* (1937, **12**, 1), and the invitation to Professor L. Sayé to read a paper on the subject before the Tuberculosis Association in April, 1936, are clear indications that chronic miliary tuberculosis is to be recognized in this country as an important clinical and pathological entity. It should be added, however, that chronic miliary tuberculosis is a somewhat protean condition, which justifies the substitu-

tion of the name "chronic disseminated tuberculosis" for "chronic miliary tuberculosis." It may appear as, or develop into, less recognized but not less important forms, which I demonstrated on the occasion of the visit of the Tuberculosis Association to the Papworth Village Settlement in March, 1934.

Chronic miliary tuberculosis may be "discrete"—that is, confined to the cortico-pleural, apical, or interlobar parts of the lung; it may produce miliary emphysema due to fibrosis of the nodules with subsequent distortion of the alveoli and small bronchi; or it may be associated with caseous pleurisy. The miliary nodules may be entirely fibrotic and form radiating scars, or they may be caseous, become confluent, and form infiltrations. These, after liquefaction, show the characteristic picture of "punched-out" cavities, sharply contrasting, because of their thin wall, with the cavities found in phthisis generally.

Chronic disseminated tuberculosis in its various forms is a chronic pulmonary lesion, haemic in origin, and associated with extrapulmonary manifestations, not seldom clinically latent; it is distinctly different from bronchogenic tuberculosis confined to the lungs. In the blood, serum substances retarding the growth of tubercle bacilli *in vitro* are often found in patients showing the haemic lesion, but are absent in those suffering from chronic isolated pulmonary phthisis. It should be remembered, however, that I was able at Papworth to produce in immunized animals the early forms leading to the isolated bronchogenic lesion by a haemic infection, which produced in a normal animal acute miliary generalization.

One point may be finally mentioned in connexion with the diagnosis of chronic miliary tuberculosis. In patients showing a chronic miliary spread it is often impossible to find evidence of tuberculosis, even on the post-mortem table. In such cases—without occupational history—I have several times found anthraco-silicotic changes near the hilum, and I regarded the miliary spread as silicotic rather than tuberculous in origin since, by experimental injection of silica, miliary nodules can be obtained identical with those mentioned. These doubts in the diagnosis of chronic miliary tuberculosis hold good in some cases recently described in the literature.—I am, etc.,

Papworth Village Settlement, Sept. 3. WALTER PAGEL.

Physical Disorder in Mental Hospitals

SIR,—The very interesting and suggestive paper entitled "Physical Disorder in 164 Consecutive Admissions to a Mental Hospital" by Dr. Robert Phillips in your issue of August 21 (p. 363) merits more than passing notice. It stirs an interesting memory of the time, many years ago, when I was in charge of the "mental" wards in the Edinburgh Royal Infirmary for nine years, during which period some fifty patients were annually certified and sent to Morningside Asylum. The fullest possible advantage was taken of the regulations of the hospital by which patients could be retained in the ward for two months' observation and treatment. Inspired by the valuable pioneer work on the blood by Dr. Lewis Bruce on the relation of physical disorder to mental disease, I directed my attention mainly to the presence of nutritional disturbances so far as these might be revealed by the examination of the urine, stools, and radiological examination of the *primae viae*. This investigation involved, *inter alia*, the careful examination of the urine for bacteria, presence of cells, etc., and of the state of the stools, notably the degree and persistence of foul odour, and general character of the flora on microscopical examination of stained films. The general conclusion drawn from lengthy observation and treatment based on its results was that a definite physical disorder was very much more common than was recognized, and that treatment of the physical condition was frequently remarkably successful in correcting the mental derangement. A record of the results was, at the instance of my friend the late Professor G. M. Robertson, the president of the Royal Medical Psychological Association, submitted at one of the annual meetings of the association in Edinburgh. At that time it was unreasonable, from the unusual nature of the lines of inquiry recommended, to expect a great deal of informed criticism. Many years' subsequent experience has not led to any material change in my opinion.

If my experience does not lead me to accept wholly Dr. Phillips's conclusions, the divergence of opinion may, I think, be explained by two points—one a question of "nomenclature," the other a varying interpretation of the word "necessity." In regard to the first, Dr. Phillips tells us that his series of cases included only five patients suffering from "alimentary *diseases*"—cancer, visceroptosis, and anorexia nervosa—and two patients suffering from "urinary *disease*"—renal calculus and cancer of the bladder. (The italics are mine.) I venture to assert that in any large series of mental cases the proportion of patients affected with notable *disorder* in these two systems is enormously greater than is recorded in his interesting series, and, further, that no sound conclusion as to causal connexion can be drawn until the physical disorder is corrected and the mental condition remains unchanged.

Regarding the second point, the limits of Dr. Phillips's paper did not allow for his presentation of data on points which are, in my view, essential in determining the correctness of the conclusion I drew from my own observations. And his statement that "the diagnoses of the cases reviewed have, when necessary, been confirmed by the consulting staff of the hospital, by laboratory methods, by *x*-ray examination, by operation, and in a few by necropsy" leaves the position unsatisfactory. Much obviously depends on the different views prevailing as to necessity.

A specially interesting point in Dr. Phillips's record is his description of fourteen cases classified as an acetonuric group. "A careful survey showed that all were in a debilitated state, with varying degrees of cachexia, exhaustion, cyanosis, furred and dried tongues, and foul stools." In relation to this, is it not a little doubtful whether Dr. Phillips is sound in his conclusion, which I assume he draws, when he states that while the general symptoms resulting in the ketosis were similar, the psychosis producing the symptoms varied, as illustrated by the names of *ten different psychoses*? (The italics are mine.)

Dr. Phillips's contribution is a noteworthy one. All will agree with his conclusions that "in a case presenting any abnormality the first essential is a thorough physical examination," and "the value of a well-equipped laboratory dealing with the problems of bacteriology, pathology, and biochemistry is emphasized." While not unmindful of newer teaching and practice, it is of value to emphasize equally the need for a wider outlook on the problem of nutrition of the mind and body alike, to cultivate the greater use of the unaided senses in diagnosis, and to remember the teaching of the ancients as revealed by the term "melancholia" for the large group of mental disorders in which a depressed state of mind is the leading feature.—I am, etc.,

Drem, N.B., Aug. 29. CHALMERS WATSON, M.D.

Insects and Disease

SIR,—In your issue of August 28 (p. 434) Dr. C. H. Foley contradicts my statement that the fever which afflicted Cromwell's army in Ireland was typhus, and asserts that the epidemic in question was plague. He mentions the outbreak of plague in Galway some weeks before Cromwell's arrival in Ireland, and the later involvement of Dublin. With these events I am familiar, like everyone else who has made any study of the history of epidemic diseases in Ireland. Had Dr. Foley been present at the lecture he would have realized that I concerned myself only with the main force commanded by Cromwell in person, which never approached Galway.

In the past no army subjected to the privations of a protracted campaign in Europe could hope to escape those twin plagues of war—dysentery and typhus—least of all in Ireland, where both diseases were normally endemic. The Lord Protector's army was no exception to this general rule. Boate, who was Cromwell's "Doctor of Physick to the State in Ireland," and who died there four months before Cromwell's return to England, says that two epidemic diseases were "very common". . . "in the English armies which since this bloody rebellion went over into Ireland"—namely, "the looseness" (dysentery) and "the malignant feaver"—under which usual name for typhus Boate gives a recognizable description of the infection. These two maladies he designates "reigning diseases" of Ireland. He tells us further, as we know from other sources, that because of its generality in Ireland the looseness is called by the English inhabitants "the country disease," and that the malignant fevers are "vulgarly in Ireland called Irish agues, because that at all times they are so common in Ireland, as well among the inhabitants and the natives, as among those who are newly come thither from other countries." Boate says nothing of plague in the Parliamentary forces. Indeed, he makes the general observation—based presumably on the fact that epidemic plague in Europe was in general a hot-weather disease—"The plague which so often and so cruelly infecteth England . . . is wonderfully rare in Ireland, and hardly seen once in an age." Nor does Cromwell himself refer to plague in his dispatches, and when commenting on his losses from disease he mentions only "the country disease" and "fever." Cromwell's lieutenant-general, Michael Jones, a fine soldier and a great man, died at this time of "contagious spotted fever." In justice to the distinguished historian whose error in confusing the Irish ague with malaria suggested my reference to Cromwell's army, I should point out that later in his account of the epidemic in question he names it correctly under one of its synonyms, and writes: "The weather was vile. The sickness among his troops was no longer malaria and dysentery but spotted fever, that plague which turned men's bones to water."

General and undefined mention of "plague" cannot be accepted as necessarily indicating bubonic plague, for the term was commonly used with even a wider application than our modern "epidemic." None the less, there seems to be no doubt that true plague was rife in several Irish towns after the Cromwellian occupation. But it is incredible that the generalized famine-pestilence which devastated the whole country could have been that disease. All the circumstances known to me of its incidence and distribution point to typhus. Unfortunately the contemporary accounts are scanty, but if the detailed descriptions of the later universal epidemics of famine-typhus in Ireland were condensed to the same compass they would give an identical picture. The medical history of Cromwell's army was repeated in the Williamite wars, thirty years later; but here, due chiefly to the industrious chaplain of Gower's regiment, we possess ample clinical details of the terrible ravages of dysentery and typhus—the latter in its most malignant form with gangrene of the extremities as a frequent complication—which reduced Schomberg's army to one-half of its initial strength.

Dr. Foley mentions the associated death of animals as excluding typhus. It is too late in the day, I suppose, to advise him to question survivors of the Irish famine-typhus of 1848 on the point. If this were possible, judging from my own experience in the past, he should have little difficulty in obtaining such accounts, the mortality in animals not being due to typhus but to the general circumstances of famine and pestilence. Nor does exalted rank confer any immunity from typhus, as witness the sad fate of the dignitaries of the High Court of Justice as late as the middle of the eighteenth century in England. Moreover, were not lice-infested senior officers one of the minor horrors of the Great War?

I suggest that Dr. Foley's "true facts," so far as Cromwell's own army is concerned, would amaze no one more than the Lord Protector.—I am, etc.,

London, Aug. 28. W. P. MACARTHUR.

The Vocal Cords in Singers and Speakers

SIR,—Mr. Victor Lambert, in his contribution to the discussion on the natural singing voice in your issue of August 28 (p. 432), seems to me to be on sound biological ground when he suggests that the difference between singers and non-singers lies in the brain and not in the larynx.

Having spent twenty-five years in contact with the natives of certain of the countries mentioned by Sir Milsom Rees, may I submit one or two observations that seem to me relevant. Writing of his experience of primitive African singing, Sir Milsom comments on its crudity and ugliness. But whatever its defects, it is admirably adapted to local requirements. To begin with, native custom and psychology offer little encouragement to singing for singing's sake, although the native can be genuinely appreciative of technical skill with either harp, drum, or flute. What is really important is power, and a European can but marvel at the carrying power of the voice in such tribes as the hillmen of Western Uganda. Group-singing among primitive natives means usually one of two things: either an arduous communal job of work or a "binge" with its attendant distractions, generally by the light of the glamorous African moon.

Before the native can grasp what singing means to us Europeans his outlook will have to change quite a lot. Missionaries have for years been teaching the African to sing. Wherever there is a school or a church—and they are everywhere nowadays—you may hear any and every day boys and girls of all ages and men and women making recognizable attempts at European tunes—that is, striving valiantly to imitate, solely by ear, sounds entirely foreign to their normal experience. The tribes along the shores of Lake Victoria do a great deal of singing in the course of their daily routine. Some of their songs are pleasing even to an ear untuned to the restricted range of primitive native music. Canoes frequently have to make long journeys across wide stretches of open lake. Singing helps the paddlers to swing together and to keep going. Without a song the men soon slack off and start talking. Certain individuals are recognized as experts. There may

be several in one crew to share the singing. The soloist shouts a line at the top of his voice and register, and then the crew grunt or yell a monosyllabic chorus, and so on for an hour or more at a stretch.

As to the rôle of the tom-tom in native singing, drums, besides adding to the noise, supply rhythm to regulate both the singer and his audience, be the responses vocal, hand-clapping, dancing, or all three. The travelling professional singer in Uganda—a true minstrel—always accompanies his song on either a small harp or a single-stringed violin. The main appeal of his performance appears to lie in the words, which are often appallingly obscene.

Singing for music's sake, the appreciation of a "good note"—or the production of one for that matter—do not, as far as I know, exist among primitive Africans. Nevertheless, the power to sing, as we Europeans sing, is there, latent in the native larynx. A visit to Namirembe Cathedral in Uganda or to the Trappist establishment at Pine Woods, near Durban, will satisfy the most exacting sceptic. Both these places possess native choirs capable of a finished rendering of the higher forms of choral music. Both will well repay a visit.

Mr. Lambert remarks, "The essence of the problem is whether there is a faculty lying dormant which can readily develop under the influence of a suitable environment." The East African evidence goes, I think, to show that there is. It is the organist, and not the organ, that is at fault.—I am, etc.,

Sussex, Aug. 31. H. LYNDHURST DUKE.

Unusual Cases of Cerebral Haemorrhage

SIR,—The following two cases of fatal cerebral haemorrhage, which occurred in my practice within twenty-four hours, may be of interest to readers of the *Journal* as the circumstances attending both cases were unusual.

CASE I

On August 22, 1937, a widow aged 69 was being driven by her grandson, aged 18, in the front passenger seat of his car from Bournemouth to Winchester, a distance of forty-one and a half miles. About five miles on the south side of the latter town the driver found himself in a long queue of cars all travelling at about fifteen miles an hour. A car towards the head of the queue braked violently, and those following did so in succession. That in which my patient was travelling succeeded in pulling up two feet behind the car in front, but an Austin Seven behind failed to stop in time and hit the back of the car in front of it with considerable force. The widow was thrown forward in her seat and then backwards, and her hat was jerked off on to the floor. She complained of nothing at the time except a pain in her right shoulder; this was inspected by a friend. All the occupants of both cars alighted, inspected the damage to the cars, exchanged names and addresses, and proceeded to Winchester.

Here my patient did a tour of the cathedral, where she complained of a headache. In the meantime the driver reported the accident to the police, who stated that as no one was apparently injured the report to the police had been unnecessary. The party remained about an hour in Winchester and then returned to Bournemouth, stopping on the wayside for a picnic tea, at which the widow took an aspirin tablet and a cup of tea and a sandwich. She arrived home about three hours after the accident, still complaining of nothing but the right shoulder.

Four and a half hours after the accident the patient vomited violently; an hour after this she vomited again, and half an hour later she became unconscious. She remained unconscious for an hour and a half before her relations realized the seriousness of her condition. When I arrived at 10.30 p.m. the patient was breathing stertorously, with extreme cyanosis. The left pupil was pin-point and the right almost so. The head, neck, arms, and upper half of the trunk were sweating profusely, while the lower half of the trunk and the legs and feet were cold. The pupils did not react to light; the knee-jerks were present and the plantar reflexes were flexor. There was incontinence of urine. I helped to remove her on a stretcher to a nursing home almost opposite her own house at midnight, where she died at 2.30 a.m.

The post-mortem examination revealed a heart weighing 14½ ounces (the normal female heart weighs from 10 to 12 ounces). There was advanced arteriosclerosis and marked atheroma of the coronary arteries. The vault of the skull was abnormally thick and heavy, and there was a linear fracture of the sphenoid bone extending from its left outer edge right across the base to the sella turcica. The whole of the surfaces of the left cerebrum and cerebellum were completely covered by blood clot.

No evidence was adduced at the inquest of the deceased having been seen to strike her head, and this point was gone into very thoroughly by the coroner; the patient herself did not complain of a blow on the head, but only of one on the shoulder. In view of the presumed absence of a direct blow on the head I put forward the suggestion, for what it is worth, that a normally thin sphenoid bone might possibly be fractured by a sudden violent jerk of the body when the base of the skull has to carry an abnormal weight of vault bone in a frail woman of 69. I made this suggestion to the coroner, and added that I thought it improbable. The jury brought in a verdict of accidental death and exonerated both drivers from blame.

The extraordinary features of this case to my mind are that the patient could have received such an extensive fracture of the base with such profuse haemorrhage into the vault with no history of a blow on the head; that she could have been driven forty-six and a half miles in a car and walked about for an hour with no complaint of head symptoms, except a headache, which does not seem to have inconvenienced her unduly; and that six hours elapsed before unconsciousness supervened.

CASE II

A garage fitter, aged 35, after helping to lift a heavy motor-coach engine, complained to the manager of "something having given way in his neck." As he seemed ill the manager sent him to the hospital, which is about seven minutes from the garage, in a car. Here he was examined, and nothing unusual was found. He complained to the house-surgeon that all he felt was a slightly stiff neck. He remained at the hospital for a short time and then returned to the garage, where he began work again. Ten minutes after his return he collapsed, and was again put in a car and brought to my house. I was called out to the gate to see him as he was too ill to move. I found him huddled up on the floor of the car with his head on the back seat, very cyanosed, with bounding and rapid pulse, and his breath coming in spasmodic gasps. I advised quick removal to hospital, but he died in the car on the way there. At the post-mortem examination the pathologist found one of several small aneurysms of the circle of Willis which was ruptured.

I also saw a third case of cerebral haemorrhage in the same week in which there were four or five fissured fractures in the central part of the frontal bone just above the frontal sinus. There was considerable haemorrhage into both eye sockets. This patient recovered.

These cases go to prove, I think, that one does not always find the classical signs of a fractured base—namely, haemorrhage from the ears, eyes, nose, or mouth—which one was taught as a student to look for; while in the third case one of these classical signs appeared in the case of a fractured vault.—I am, etc.,

Bournemouth, Aug. 29.

Tennis Elbow

SIR,—Glad though I am to find Mr. G. K. McKee (*Journal*, August 28, p. 434) and myself in such complete agreement on the pathology of tennis elbow, I think the time is not ripe for changing its name to "traumatic periostitis at the origin of the extensor carpi radialis brevis." At the discussion of this subject in the Section of Orthopaedics at Belfast only two of the nine members who are reported as having spoken were in favour of this conception. Even Mr. G. P. Mills, whose manipulation consists in putting a sudden great strain on the extensor origin at the epicondyle, is so unimpressed by the theory of his very successful method of treatment that he attributes tennis elbow to an affection of the coronary ligament. Until, therefore, the majority of the profession have been converted to the idea of a traumatic periostitis by the, to my mind, conclusive arguments put forward by Mr. McKee in his letter and by myself in the article he refers to, it is premature to label tennis elbow with a name that precludes a difference of opinion on the pathology. For the present it would seem that the non-committal historical term will have to be retained.

In 1873 Runge described, but did not name, a case of inability to write associated with tenderness on the lateral humeral condyle. Morris, in 1882, noted a condition analogous to rider's sprain, which he called "lawn *tennis* arm." An annotation in the *Lancet* in 1885 drew attention to the number of sufferers from "tennis elbow," whose plaintive letters had recently appeared in the lay press. Remak (1894) and Bernhardt (1896) agreed with Runge that it was a periosteal tear due to occupational over-use of the extensor muscles of the forearm. *Couderc* (1896) called it a ruptured epicondylar tendon, Féré (1897) épicondylalgie, and Franke (1910) epicondylitis. *Osgood* (1922) suggested radio-humeral bursitis, thereby incriminating the bursa discovered by Monro in 1788. Schmidt (1921), on the other hand, believed the fault to lie in the subcutaneous epicondylar bursa, first described by Schreger in 1825. On the whole the more recent English writers have called it tennis elbow, while Continental writers have preferred epicondylitis, but all are agreed that tennis is by no means the only cause of the condition, and that the bony epicondyle is seldom, if ever, inflamed. However, until agreement becomes general ,the name "tennis elbow" will have to remain, since it does not imply the acceptance of any particular theory on the pathology. But I hope that this agreement will not be long delayed, so that Mr. McKee's excellent suggestion may become universally acceptable.—I am, etc.,

London, W.1, Sept. 1. J. H. CYRIAX.

A Case of Ether Convulsions

SIR,—Recent interest in this condition has prompted us to submit an account of a typical case which occurred while under our care.

The patient is a well-built boy, aged 16, who was admitted to hospital twenty-four hours after the onset of an attack of acute appendicitis. He was obviously toxic, with a temperature of 101° and a pulse rate of 90. Since operation his family history has been carefully investigated, and there is no hereditary disturbance or epileptic tendency.

The operation was performed on a very hot and thundery summer afternoon. Induction was started at 4 p.m., three-quarters of an hour after the hypodermic injection of omnopon 1/6 grain and scopolamine 1/300 grain, with an ether-chloroform mixture in the proportion of three to one. Induction was smooth and lasted ten minutes. It is interesting to note, first, that no atropine was given, and, secondly, that the ether had been in the drop-bottle since an emergency operation the previous night and so had presumably been exposed to more actinic light than usual, especially as the bottle was not amber-coloured. The operation had lasted half an hour when the anaesthesia was deepened preparatory to sewing the peritoneum. Throughout this time the patient had been breathing well and was a good colour, nothing abnormal being noted except that he was sweating profusely, which was in some measure due to the temperature of the day.

The first sign was a stiffening of the jaw, followed by twitching of the eyelids, which spread to the limbs and gave way to clonic movements of the whole body. The breathing, colour, and pulse were still good. The patient was then deeply anaesthetized with chloroform, and evipan was prepared but not used; it would have been quite impossible to give an intravenous injection in the presence of such violent convulsions. The convulsions became much less violent as soon as the chloroform was given, but were as frequent. The operation was hastily completed, and as the skin was being stitched the patient went into tonic spasm, including spasm of the larynx, becoming very cyanosed, with a marked change in the pulse, which became thin, thready, and rapid. Oxygen was administered and the spasm slowly passed off, the pulse improved, and the convulsions ceased. Convalescence was uneventful, although the temperature was raised for the first few days.

We have been able to trace thirty-two references to this condition in the literature, all published since 1927. Most writers are agreed that the condition carries a mortality of at least 50 per cent., and tends to occur in hot weather in young people who are suffering from an acute illness—often appendicitis. Many suggestions have been put forward to account for the condition, none of which are entirely satisfactory. Wilson, who originally described the condition, decided after exhaustive inquiries that it was due to impurities in the ether—acetaldehyde and "peroxides," which develop if the ether is exposed for any length of time to the action of light, especially actinic. Our case would appear to support this. Other suggestions have been that there is some personal or familial idiosyncrasy, or that the condition is due to the administration of atropine, the dose having been repeated in some cases following an unforeseen delay in starting the operation. In the case we have described no atropine was given at all.

Finally, it is interesting to note that the condition of the patient improved as soon as chloroform was administered. This is contrary to the general consensus of opinion, which advises the intravenous injection of evipan. Such an injection would have been technically impossible in the circumstances. There was no tendency to relapse or to cardiac failure after the cessation of the convulsions, as has been recorded after the use of evipan, following which death has been reported several hours after an apparent recovery.

We wish to record our thanks to Mr. E. S. Lee for his kind permission to publish this case.—We are, etc.,

D. N. MATTHEWS.
London, W.1, Aug. 29. EDWARD GEAL.

Anti-spasmodic Drugs in Labour

SIR,—The reference in the *Journal* of July 10 (p. 58) to an article by Drenkhahn in *Med. Welt* of March 20, 1937 (p. 394), states that the author arrives at his conclusions "on purely theoretical grounds." In his original paper Drenkhahn draws certain theoretical deductions, which, however, he bases upon the pharmacological experiments of C. v. Schindler and on the clinical observations of L. Alexander. The fact that atropine causes a relaxation

of the sphincter of the portio vaginalis of the uterus, while it has no or only a slight stimulating effect on the muscles of the body of the uterus, was already well known to a number of authors, who have proved this statement in several hundred clinical cases and have contributed a certain amount of work on the subject of the pharmacological action of the drug in obstetrics.

May I record the experiences I have had in more than forty obstetrical cases, using syntropan (Roche) instead of atropine. Syntropan is a synthetic ester of tropic acid, whereas atropine is a tropic ester of tropine. Syntropan has only a very slight action on the heart, circulation, secretory glands, pupil, and accommodation. It was therefore found to be harmless and well tolerated, no undesirable after- or by-effects (palpitation, rashes, sight trouble, dryness of the mouth) being observed.

The procedure in every case was to administer syntropan rectally when the pains came on regularly, and at intervals of not more than ten to twelve minutes. After one to one and a half hours another suppository of syntropan was introduced. The effect became apparent after about fifteen minutes, when the pain was alleviated, while the force of the uterus contractions in no way decreased. The patients soon felt much more comfortable. The dilatation of the cervix was hastened and no narcotics were used except, of course, a little ether at the end of the second stage. The first stage was shortened by two to four hours, as has also been recorded by several other authors, and the time of the confinement very much reduced. The patients in most cases were normal anatomically, but they included a preponderance of elderly primiparae, and in quite a number the foetal head was slightly overlapping. In no case was there a secondary uterine inertia, and, thanks to the relaxation of the painful spasms, the women developed sufficient reserve power and steadiness, so that the ultimate result was satisfactory for both mother and child without the necessity of operative intervention.

I made the same observations as Alexander, Kreis, Gammstadter, and several French authors, and I wish to confirm the conclusions of Drenkhahn—namely, that the employment of spasmolytics in obstetrics is useful, and that atropine has certainly a good influence in labour, even in normal cases. (Syntropan, having a similar action on the uterus, but being devoid of by-effects, is better tolerated and more to be recommended.) Syntropan brings about a marked relaxation of the sphincter of the cervix uteri and helps to increase the polarity of the womb. Atropine and syntropan are both parasympathetic depressants. "The uterus receives both motor and inhibitory fibres from the sympathetic. There is no supply by the sacral autonomic (Wright)."

The question as to how the polarity of the womb and the action of atropine and syntropan on the cervix and uterus body is brought about still remains open.—I am, etc.,

London, N.W.6, Aug. 24. F. E. HIRSCH.

N. J. Rousset (*J. Méd. Lyon*, May 23, 1937, p. 283) draws attention to the dangers of manicure. The main risk is an infection of the perionychial tissues caused by repeated slight injuries to the cuticle while it is being pushed back. These result in a staphylococcal infection of the nail matrix and of the surrounding tissues. The author distinguishes three forms of infection: (1) a purely inflammatory form, (2) a suppurating form, and (3) a mixed form. The nail itself is usually not affected, but in some cases transverse grooves may appear, and may be so deep as to cause complete separation between the different parts of the nail. The grooves then fill with a fleshy granulation not unlike botryomycoma. The differential diagnosis is usually easy, but certain forms of syphilitic, eczematous, inflammatory, and chemical dactylitis may closely simulate the affection described.

Obituary

GEORGE EDWARD LOVEDAY, M.A., M.B.

Director of the Clinical Laboratory, Royal Infirmary, Manchester; Reader in Clinical Pathology, Manchester University

We announce with regret the death of Dr. G. E. Loveday, which took place in tragic circumstances at Sheringham. He had apparently been in poor health for some months, although he had said nothing about it to his colleagues.

George Edward Loveday was born in 1876, and was educated at Giggleswick and Caius College, Cambridge, where he took his B.A. in 1898 and spent an extra year studying pathology in its general and clinical aspects. He completed his medical course at St. Bartholomew's Hospital, and qualified M.R.C.S., L.R.C.P. in 1902; in 1903 he proceeded to the M.B. and M.A. of Cambridge University. Hospital appointments followed at Addenbrooke's and the Salop Infirmary, and in 1905 he joined the staff of Sir Almroth Wright's laboratory at St. Mary's Hospital, London. Here he studied opsonins and therapeutic inoculation, and in 1906 was appointed to give instruction in Wright's methods for three months at the Manchester Royal Infirmary. Some time previously Loveday's sister had married Sir Arthur Schuster, the professor of physics at Manchester University, and it was probably this connexion which attracted him to the city in which he was destined to spend the rest of his life. Loveday's work so greatly impressed all with whom he came into contact that he was appointed director of the clinical laboratory within a year of his arrival, a position he still held with great distinction at the time of his death. It was an ideal post, for it gave him plenty of time and facilities for outside consultant work, and his services were freely used. At the time of his appointment the laboratory staff consisted of himself and a boy, but under his directorship it gradually grew to its present personnel of sixteen, and he became responsible for the administrative charge of a vast amount of work covering the whole scope of clinical and pathological practice of a large teaching hospital. In addition he held the readership in clinical pathology at the University, and taught clinical pathological methods to generations of students. His laboratories, too, had to be extended, and the designs and plans were largely his.

Throughout his life Loveday remained a devoted disciple of Wright and Wright's methods. His main interests were in the serological and bacteriological side of clinical pathology, but he was not greatly interested in biochemistry. He was expert in vaccine therapy, and devoted a large amount of his time to this particular study. He excelled in the application of serological and vaccine therapy as applied to each particular case, and as his clinical judgement and balance were good his opinion in cases of infection was extremely valuable. Loveday was a great believer in small doses, and his experience convinced him that the population of Manchester as a whole could not stand the doses usually recommended and employed in London. Careful records of the dates, dosage, and effects produced were kept, and these lay in neat piles around him on his desk. Woe betide anyone who disarranged them! The cares of a very busy practice unfortunately prevented the publication of much valuable statistical material. His work was characterized by its accuracy, neatness, and thoroughness. It was personal and painstaking to the last degree, and he never delegated important work to others. His technical skill was extraordinary, and nowhere was it

more evident than in the neatness of his blood transfusion work. He was something of a martinet, and would brook no interference in his laboratory from anybody. Freely consulted by everyone on the hospital staff, he liked nothing better than to discuss a slide or the treatment of a case with one of his colleagues, but should the latter betray the least ignorance on a pathological matter the scorn in Loveday's voice was unmistakable. It would quickly pass, however, and the visitor would leave the laboratory with much valuable information.

Loveday was a man of rare character and was respected by all, especially by the numerous people who learned their clinical pathology by working in his department and were able to recognize the charm of a character that was not always apparent on casual acquaintance. On the outbreak of the war he was appointed pathologist to the 57th General Hospital, at first in Manchester, but later, in 1917, in France. It was on the journey over that he first met the lady who became his wife. He had three children, who were unfortunately all delicate. In May this year his eldest son went as a King's Scout to the Coronation. Almost at once on his return to school he developed meningitis and died. It was a terrible blow to Loveday, and must have been the beginning of the end.

Professor Albert Ramsbottom writes: Dr. Loveday's tragic death has left a gap in our medical school which it will be difficult to fill, and has deprived many of us of a very staunch friend. The position he held at the Manchester Royal Infirmary was, I think, unique, so varied were his duties, and upon every branch he brought to bear a master mind. It is difficult to imagine a more efficient director of a clinical laboratory, for he combined a mastership of technique with an astonishing capacity for work, which he was ever ready to place at your disposal; his aid was eagerly sought by all who realized the value of his help in solving clinical problems. He had a shy and retiring temperament, which was apt to be mistaken for unfriendliness, but closer contact soon revealed his true kindly nature. In his early years in Manchester I am sure that his health was maintained by occasional fishing and skating holidays, to both of which pastimes he was devoted. The ever-increasing demands, however, of medicine upon the ancillary services made a greater call on his time, and, despite repeated warnings from his friends, led him gradually to restrict his leisure; as time passed it was noticeable to his colleagues that the ever-increasing strain of work was taking its toll of a constitution at no time robust. Coupled with this came the tragedy in May of the death of his elder son—a blow which plunged him into a grief from which he never recovered and ultimately led to his breakdown in health. He leaves a widow, a son, and a daughter, to whom our whole-hearted sympathy goes out.

CHARLES CARTER BRAINE, F.R.C.S.

We regret to announce that Mr. Charles Carter Braine, the distinguished anaesthetist, died on September 1, aged 78, at Grove End Gardens, N.W. He had been in ill-health for the past year or two, and had recently undergone an operation. He was educated at Charing Cross Hospital, taking the M.R.C.S., L.R.C.P. in 1887, and the F.R.C.S.Eng. in 1890. He filled for many years the position of anaesthetist at Charing Cross Hospital, and also at the Royal Dental and St. Peter's Hospital for Stone, following in all these appointments his well-known stepfather, F. Woodhouse Braine, F.R.C.S. He was during the great war anaesthetist to the King George Hospital, London.

Carter Braine's contributions to literature included "Artificial Respiration and Resuscitation," *Quain's Dictionary of Medicine*, third edition; "A Safety Junker Inhaler," *British Medical Journal*, 1892; "Position in Kidney Operations," ibid., 1900; "Experience of Anaesthetics in 200 Consecutive Cases of Prostatectomy," *Trans. Soc. Anaes.*, 1906. He was joint author with Arthur Underwood of *Notes on Anaesthetics in Dental Surgery*, second edition.

He was a man of great experience, and could be relied upon to deal with any emergency, imperturbability being his chief characteristic. Carter was a modest man and an agreeable colleague, and it was a lasting pleasure to call him "friend" and to know him intimately as "Chas." As an instance of his generous nature it may be mentioned that, hearing that the son of the writer of this note had suffered from whooping-cough, Carter insisted upon giving up his house at Bognor for the boy's benefit. He devoted much of his time to Freemasonry, and held many of the highest ranks in the craft—Grand Officer, Harvey Chapter, and member of La Chère Reine, Cavendish, and other lodges. Mrs. Carter Braine for more than forty years was a most devoted helpmate. She and the family of two sons survive. The elder, John Francis Carter Braine, M.D., F.R.C.S., is assistant surgeon to the actinotherapeutic department of Guy's Hospital.

DAVID CONNOR KIRKHOPE, M.D., D.P.H.,

Formerly Medical Officer of Health for Tottenham

The death occurred at a London nursing home on August 25 of Dr. D. C. Kirkhope, who, at the age of 65, had only recently retired from the post of medical officer of health for the borough of Tottenham.

Dr. Kirkhope received his early medical training at Queen's College, Belfast, and Glasgow University, and qualified M.B., Ch.M.Glas. in 1895, proceeding to the M.D. degree in 1906. After obtaining the D.P.H.Cambridge he was called to the Bar of Gray's Inn and the Middle Temple. In 1909 he was appointed assistant medical officer of health for the borough of Leyton, and in 1913 succeeded the late Dr. Butler-Hogan as medical officer of health for Tottenham, which position he held with marked distinction for twenty-four years until his retirement in May of this year.

During more than a quarter of a century of public health service Dr. Kirkhope took an active part in the growth of preventive medicine not only in Tottenham itself but in the service as a whole. As a member of the British Medical Association for more than twenty-five years Dr. Kirkhope was chairman of the North Middlesex Division in 1927–8, honorary secretary to the Section of Preventive Medicine at the Annual Meeting of the Association at Cardiff in 1928, and acted as representative in the Representative Body on seven occasions between 1925 and 1932. Dr. Kirkhope was a man of high principle and zeal, and at his retirement his long record of work in Tottenham brought forward from members of the town council and representative bodies and from colleagues many expressions of appreciation indicating his undoubted popularity and the esteem and respect in which he was held. He was looking forward to a world tour in September, during which he had hoped to visit two of his sons in Canada, and this must be an added grief to his surviving widow, two daughters, and three sons.

A colleague writes: The position of medical officer of health for a large borough such as Tottenham is a responsible one and needs moral courage and administrative ability in the man who occupies it. Dr. Kirkhope

possessed both these qualities. During his long term of office there was great development in the social services of the borough. The public health department, when his term of office expired in April last, embraced clinics for minor ailments and for the eye, ear, teeth, orthopaedics, and anti-diphtheria inoculation. The maternity and child welfare work was very well organized, extensive, and successful. Dr. Kirkhope was keen on his work and a friend to the members of his staff, medical and clerical. Because he was capable and straight he won their confidence and inspired their loyalty. He could make a good speech, and he wrote clear and good English, as can be seen from his annual reports. He was also a skilled musician. He will be missed especially by the older members of the community. Those of us who were regularly in touch with him will look back with gratitude to him for good advice, ready help, and friendliness.

MELVILLE MORTIMER ADAMS, M.B., B.S.,
Pretoria

The death on August 6 of Dr. M. M. Adams came as a great shock to his many friends. Dr. Adams was a Transvaaler by birth, being born in Lydenburg on November 26, 1884. He was at school in Pretoria, subsequently joining the King Edward Grammar School, Chelmsford, where he remained until he matriculated at London University. His medical studies were at Guy's Hospital, where he remained until he qualified with the English Conjoint diplomas M.R.C.S., L.R.C.P. In 1912, having taken the degrees of M.B., B.S.Lond., he returned to Pretoria and became house-surgeon to the Pretoria Hospital. At the outbreak of the great war he was with the South African Forces in South-West Africa. On the completion of that campaign in 1915 he returned to Pretoria for a short time, but in the same year he went to England and joined the R.A.M.C. as a lieutenant. He was sent to Gallipoli, and later was attached to Lovat's Scouts in Egypt. At the end of 1916 he was attached to the 2nd South African Infantry with the rank of captain. He was in France in June, 1918, and was present at the actions at Beaurevoir and Le Cateau. He was demobilized in Capetown in October, 1919, and returning to Pretoria went into general practice, which he continued to his death.

Dr. Adams was for many years on the honorary visiting staff of the Pretoria General Hospital and was honorary lecturer to the nurses there until his death. He was at one time president, and previously secretary, of the Pretoria Division of the S.A.M.A. (B.M.A.). He was a prominent Freemason and a Past Master of the Transvaal Lodge E.C. He was an enthusiastic golfer, and belonged to nearly all the golf clubs in Pretoria. His funeral was attended by a large contingent of the hospital nurses in uniform, by his colleagues of the visiting staff, and by representatives of all sections of the community.

H. P. V.

We announce with regret the death, at the age of 40, of Dr. William Melrose Cumming. Dr. Cumming took the M.B., Ch.B. at St. Andrews in 1922, and since his interests were even at that time in public health, and particularly in the treatment of tuberculosis, he went on to take the D.P.H. in 1925, the Ph.D. in 1926, and finally the M.D. with a gold medal in 1927. He was for a short time assistant to the Professor of Bacteriology at University College, Dundee, and later became assistant medical superintendent of the Fife and Kinross Joint Sanatorium. After that he was for a short time senior assistant medical officer to the Grove Park Hospital, Lee. He was appointed medical superintendent of the Grassington Sanatorium in May, 1926, and was succeeded by Dr. R. S. Donaldson in June, 1935. His publications included an article on the serology of the bovine type of tubercle bacillus, published in 1925, the results of some work done two years later on the pseudo-haemolytic streptococci isolated from the sputum in pulmonary tuberculosis, and more recently he contributed to a symposium on the infectivity of tuberculosis, which appeared in the *British Journal of Tuberculosis* in 1932.

The death of Dr. ANTOINE BÉCLÈRE robs France of one of her most gifted and versatile radiologists. As a young man he was already beginning to make his mark in bacteriology when Röntgen's discovery of the *x* rays induced him to throw all his energies into this field in which he played so distinguished a part that he became president of the Société de Radiologie de France. He was also at one time president of the French Academy of Medicine. Only a few years before his death Béclère took up with much enthusiasm the work of his younger days and published bacteriological studies, several of which were concerned with influenza.

The Services

DIRECTOR-GENERAL, A.M.S.

The War Office announces that Major-General W. P. MacArthur, D.S.O., O.B.E., M.D., D.Sc., F.R.C.P., F.R.C.P.I., Honorary Physician to the King, has been selected to succeed Lieutenant-General Sir James A. Hartigan, K.C.B., C.M.G., D.S.O., M.B., D.Ch., Honorary Physician to the King, as Director-General of Army Medical Services when the latter completes his tenure of office on March 1, 1938.

General MacArthur graduated in the Royal University of Ireland from Queen's College, Belfast, in 1908 and was commissioned in the R.A.M.C. in 1909. For his services in the great war he was awarded the D.S.O. in 1916 and the O.B.E. in 1919. Since then he has held the appointments of Professor of Tropical Medicine at the Royal Army Medical College, Consulting Physician to the Army, Deputy Director-General at the War Office, and Commandant and Director of Studies at the Royal Army Medical College, which appointment he now holds. He was appointed Honorary Physician to the King in 1930. He was elected Fellow of the Royal College of Physicians of Ireland in 1913 and of the London College this year. He is an honorary D.Sc. of Queen's University, Belfast. He was Thomas Vicary Lecturer before the Royal College of Surgeons of England in 1931, and Chadwick Medallist in 1935.

DEPUTY DIRECTOR-GENERAL, I.M.S.

Lieut.-Colonel E. G. Kennedy has been appointed Deputy Director-General, Indian Medical Service.

ARMY DENTAL SERVICES

The War Office announces that Colonel D. Clewer, Inspector of Army Dental Services in India, has been selected for appointment as Director, Army Dental Services, The War Office, in succession to the late Colonel J. V. M. Byrne.

DEATHS IN THE SERVICES

Colonel THOMAS EVELYN FIELDING, D.S.O., late R.A.M.C., died at Hindhead on August 9, aged 65. He was born on July 27, 1872, and educated at Trinity College, Dublin, where he graduated B.A., M.B., B.Ch., and B.A.O. in 1897. Entering the R.A.M.C. as lieutenant on April 25, 1900, he became lieutenant-colonel on December 26, 1917, and retired as colonel in 1930. He served in the South African War of 1900-2, when he took part in operations in the Transvaal, the Orange River Colony, and Cape Colony, served in the defence of Fort Itaka, on the Zululand border of Natal, in October, 1901, was mentioned in dispatches in the *London Gazette* of September 10, 1901, and January 17, 1902, and received the Queen's medal with three clasps and the King's medal with two clasps. In the war of 1914-18 he served as A.D.M.S. of the 28th

Division in the Salonika Force in the army of the Black Sea and in Constantinople; was mentioned in dispatches in the *London Gazette* of October 19, 1914, and June 25, 1915, and received the D.S.O.

Surgeon Captain WILLIAM BASTIAN, R.N. (retired), died in University College Hospital, after five weeks' illness, on August 2, aged 62. He was the third son of the late Dr. H. Charlton Bastian, F.R.S., and was educated at University College School, Hampstead, and at University College Hospital, and qualified M.R.C.S., L.R.C.P. in 1900. After qualifying he joined the Navy, became surgeon commander on August 2, 1914, and retired as surgeon captain on June 8, 1925. Captain Bastian was particularly interested in the problem of prevention of venereal disease in the Navy. He served during the war of 1914-18. He had been a member of the British Medical Association since 1907, and served on the Naval Medical Service Subcommittee in 1919-20. Since his retirement he had resided at Loughborough. He leaves a widow, one son, and two daughters.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

Titles of medical degrees were conferred by diploma on the following members of Girton and Newnham Colleges during July:

M.B., B.CHIR.—M. B. Billington, G. M. S. Caldwell.
M.B.—E. M. Wright.

UNIVERSITY OF LONDON

A course of lectures and clinical instruction for medical practitioners on problems connected with retarded and difficult children has been arranged by the University Extension and Tutorial Classes Council, in co-operation with the Central Association for Mental Welfare, and will be held from Monday, November 1, to Saturday, November 6. The course is open to those medical practitioners who have already attended the course on mental deficiency and allied conditions, or who have specialized experience approved for the purpose of the course. The lectures will be delivered at the University of London, Senate House, Montague Place, W.C., unless otherwise stated on the students' time-tables, and will be given from 10 a.m. to 12.30 p.m. each day. Detailed time-tables will be sent by October 26 to each person proposing to attend the course, and in order that the practical work may be satisfactorily arranged it is important that forms of application should be filled in and returned not later than October 9. The University will grant certificates of attendance to those who attend regularly taking both theoretical and practical work. The registration fee is 10s. 6d. and the fee for the course £3 3s. All communications should be addressed to Miss Evelyn Fox, c/o University Extension Department, University of London, W.C.1.

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated:

SURGERY.—J. B. Alexander, F. Bastawros, J. D. Buckner, I. W. Claiman, T. Gadian, J. B. Good, W. A. Groom, E. de C. Kite, B. W. S. Spurgin, A. T. Rogers, W. E. Young.

MEDICINE.—A. A. Beazeley, T. Gadian, O. D. Gilmore, H. W. John, K. G. Pascall, T. van der Walt.

FORENSIC MEDICINE.— A. A. Beazeley, T. Gadian, O. D. Gilmore, B. T. Jones, K. G. Pascall, T. van der Walt.

MIDWIFERY.—H. P. Anderson, A. Backman, J. A. W. Berryman, H. B. O. Cardew, D. H. Fowler, M. W. Hemans, D. C. Light, G. MacBain, T. van der Walt.

The diploma of the Society has been granted to A. A. Beazeley, I. W. Claiman, O. D. Gilmore, H. W. John, E. de C. Kite, K. G. Pascall, and T. van der Walt.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

At a meeting of the Royal Faculty of Physicians and Surgeons of Glasgow, held on September 6, with Professor Archibald Young, the president, in the chair, the following were admitted Fellows of Faculty: Paresh Nath Baruah, M.B., Alfred Finlay Brown, M.B., Ch.B., Enrique Eduerdo Krapf, M.D., Edwin Stewart Lawrie, M.B., Ch.B.

Medical News

The eleventh Congress of the Société Internationale de Chirurgie will be held in Vienna from September 19 to September 22, 1938, under the presidency of Professor Rudolph Matas of New Orleans.

All qualified medical practitioners interested in plastic surgery are invited to attend the second European Congress of Structive (Plastic) Surgery, which is to be held at the Royal Society of Medicine, London, on October 6 and 7. The office of the congress is at 149, Harley Street, W.1, to which acceptances of the invitation, accompanied by the congress subscription of £1 and requests to join in the discussions, should be forwarded not later than September 25.

The first world congress on the human voice will be held during the Paris Exhibition from September 19 to 28 in the Health of Jena and the Marcelin Berthelot centre. The programme will consist of two parts—namely, the production, accomplishments, and education of the direct voice, and the microphone voice.

An International Congress of Anaesthetics will be held at Chicago from October 25 to 28, and will be followed by a supplementary congress at the University of Wisconsin. Further information can be obtained from the general secretary, Dr. D. F. McMechan, 318, Hotel Westlake, Rocky River, Ohio.

The annual dinner of the old students of the Medical College of St. Bartholomew's Hospital will be held on Friday, October 1, in the College Hall, Charterhouse Square, at 7.30 p.m., with Dr. C. M. Hinds Howell in the chair.

The annual dinner of the Middlesex Hospital Medical School will be held at the Savoy Hotel on Friday, October 1, at 7.30 p.m.

The annual prize distribution of St. George's Hospital Medical School will be held in the board room of the hospital on Saturday, October 2, at 3 p.m., when Dr. W. R. Halliday, principal of King's College, London, will deliver the inaugural address.

The William Gibson Research Scholarship for Medical Women of the Royal Society of Medicine has been awarded to Dr. Nancy E. G. Richardson of London. Dr. Richardson proposes to carry out research on carbohydrate metabolism in pregnant and lactating women in relation to the principles secreted by the anterior lobe of the pituitary.

The *Proceedings* of the Staff Meetings of the Mayo Clinic of July 28 contains an announcement that the residence of Dr. and Mrs. W. J. Mayo is to be converted into an establishment to assist the educational aims of the Mayo Foundation and of the University of Minnesota. The residence and the east half of the block on which it stands will be transferred by deed for the Foundation to a board of trustees, and Dr. Mayo intends to endow the property sufficiently to prevent taxes and general maintenance becoming a burden on the Foundation.

A serious outbreak of infantile paralysis in Melbourne (Australia) is reported in the *Times* of August 30. Up to August 29 the total number of cases was 185, with thirteen deaths, including four adults. Over 100 schools have been closed, and special education broadcasts have been arranged for children kept at home by their parents. Country areas are demanding that children arriving from Melbourne shall be isolated, and Tasmania is making a similar stipulation. A police force has been sent from Sydney to patrol the Victorian border to prevent the entry into New South Wales of children without medical certificates of twenty-one days' isolation.

The issue of the *Journal de Médecine de Lyon* for August 20 is devoted to diseases of the alimentary system, that of the *Journal de Médecine de Paris* of August 19–26 to school medicine and physical education, that of *Bulletin Médical* of August 28 to biology, and that of *Paris Médical* for September 4 to ophthalmology, oto-rhino-laryngology, and stomatology.

The *Practitioner* publishes this month an extra number (price 1s.) to commemorate its move to a new home in the medical quarter of London at 5, Bentinck Street, W.1. This special issue is admirably produced. The Editor, Sir Humphry Rolleston, contributes a short foreword; Dr. C. H. Reilly, emeritus professor of architecture in the University of Liverpool, discusses the design of the new building; and Mr. Walter Goodesmith describes the installation, equipment, fitments, and furniture.

It was announced in the *Journal* of July 8, 1933 (p. 71) that a supply of serum obtained from patients convalescent from acute poliomyelitis would be issued by the Public Health Department of the London County Council. We are now informed by Dr. J. A. H. Brincker that serum from convalescent poliomyelitis cases is no longer available for issue from the Western Hospital.

On September 6 Lady Pearson, widow of Sir Arthur Pearson, the founder of St. Dunstan's, laid the foundation-stone of the new St. Dunstan's Home which is being erected at a cost of more than £100,000 on the cliffs at Ovingdean, near Brighton. Sir Ian Fraser, chairman of St. Dunstan's, presided at the ceremony, and after speeches of welcome by the Mayors of Brighton and Hove the scheme was explained by Colonel E. M. Ball, chairman of the building committee.

The postgraduate course on the modern treatment of fractures which has just been concluded at the Bristol Royal Infirmary was so successful that it is proposed to hold a similar course, lasting one week, in January, 1938.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House, Tavistock Square, W.C.1.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are
EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Attiology Westcent, London.*
SECRETARY, *Medisecra Westcent, London.*

The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh), and of the Office of the Irish Free State Medical Union (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone 62550 Dublin).

QUERIES AND ANSWERS

Treatment of Mycosis Fungoides

"M. C." asks for advice on the treatment of a patient suffering from mycosis fungoides which has progressed rapidly in spite of treatment by *x* rays and malarial therapy.

Buccal and Lingual Ulcers

"PUZZLED" writes: A married woman, aged 27, who recently consulted me, states that she has had recurrent painful ulcers of the tongue and buccal mucous membrane since an attack of influenza five and a half years ago. I find that the Wassermann reaction is negative, scrapings of the ulcers show no evidence of a fungus, and examination of the blood excludes the anaemias. *X*-ray examination of the alimentary tract done some months ago was also said to be negative. I should be grateful for any suggestions as to the causation and treatment of this condition.

Splitting Finger-nails

Dr. R. A. GARDNER, in reply to Dr. Stiven (*Journal*, August 7, p. 306), writes: For the splitting of finger-nails, probably due to over-exposure to *x* rays fifteen years ago, some authorities recommended "durafix." If this is not obtainable in Cairo, ciné-film cement—celluloid dissolved in amyl acetate—would probably be efficient in filling the cracks and thus preventing their irritation. Although many of the essential facts regarding protection from radiation were known at the beginning of this century, the first safety recommendations were issued in England in the early twenties only. Even so late as the present year they had not been adopted fully by the principal hospital in Cairo. In this regard there is much to be said for the action of the Italian Government in requiring the licensing of *x*-ray installations. *X*-ray "screen" examination should be a harmless procedure, but unfortunately it gives no warning of the severe injury it is capable of producing under certain conditions to both doctor and patient.

LETTERS, NOTES, ETC.

Vagitus Uterinus

Dr. E. A. DOUGLAS writes from Lucknow: Vagitus uterinus appears to be a sufficiently exceptional condition to make it worth while reporting a case we had in the Kinnaird Hospital on February 17, 1937. The patient, a Mohammedan primipara of 32 years, married eighteen years, who had been attending the ante-natal clinic since her third month of pregnancy, was admitted to hospital on February 4, 1937, at almost full term. The presentation was transverse, the foetal heart good. The pelvic measurements were apparently normal, but there was cervical erosion and a vaginal discharge. Attempts to correct the position of the child failed. On February 7 the presentation was breech, but later reverted to transverse. On February 17, early in the morning, the patient passed a quantity of liquor amnii, but there was no pain until 9 a.m., when a vaginal examination was made. The os was two fingers dilated, the membranes were ruptured, and an elbow was presenting. It was not then possible to perform version. I first saw the patient at 12.30 p.m. the same day. The pains were strong; head was still lying in a transverse position, though not actually in the iliac fossa; the foetal heart was good. At 1 p.m. the patient was anaesthetized, and I found the os almost fully dilated, with both hand and foot presenting. Version was easy. The presenting foot, which proved to be the right, was brought down. I was about to put my hand into the vagina to bring down the second foot when the baby drew up its foot, and we heard a muffled sound coming from the abdomen. Five of us who were present in the labour ward definitely heard the cry. I brought down the second leg, and again the baby cried. There was no delay in delivering the shoulders, but the head stuck, and I quickly delivered with forceps on the after-coming head. The baby, a female weighing 5 lb., was born in a state of blue asphyxia, but very soon recovered.

Parathyroid Extract and Enlarged Prostate

Dr. F. O. TAYLOR (Coldingham, Berwickshire) writes: Mr. A. P. Bertwistle describes a dramatic "cure" "under the exhibition of parathyroid extract grain 1/2." If I had known of this treatment last year, and found it so successful, I should have been able to ease much suffering. As I should like to know more about this treatment, perhaps Mr. Bertwistle will state the manner in which he "exhibited" the 1/2 grain of parathyroid extract. These notes would be of much greater use if just a little more detail were given us to bite upon.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

188 Pyrexia in Myeloid Leukaemia

According to J. OLMER and J. BOUDOURESQUES (*Ann. de Méd.*, April, 1937, p. 265), although uncommon, cases have been recorded which bridge the gap between myeloid leukaemia and acute lymphatic leukaemia. They prove that these conditions, although different in their course and symptoms, are expressions of the same pathological process. A clear example of a transitional condition is acute myeloblastic leukaemia, in which an acute malady, usually with splenomegaly but without buccopharyngeal symptoms or general haemorrhages, coexists with a leukaemia in which the blood contains great abundance of young cells. These, however, are further differentiated than the undifferentiated cells of acute leukaemia. Seven such cases are summarized. The writers draw special attention to pyrexia in myeloid leukaemia. It is often stated that it does not occur, but it may be noted early in the disease, and there may be repeated acute febrile exacerbations, chronic pyrexia, or terminal pyrexia. Acute transitory pyrexia is less common than the preterminal; both are accompanied sometimes by the appearance in the blood of myeloblasts and even more immature cell-forms, and by a tendency to haemorrhage. In the former considerable improvement usually occurs after radiotherapy. Eight cases are summarized which show, however, that febrile attacks occur in some cases of myeloid leukaemia without any important myeloblastic reaction in the blood, spleen, or marrow. In one of the writers' cases pyrexia, thought to be due to tuberculosis, preceded the discovery of splenomegaly by eight months. The cause of the fever is obscure, since blood cultures have nearly always been negative; the tuberculous infection which coexists, according to some authors in two-thirds of cases, is probably secondary, and massive blood-cell destruction is not always present. In general, febrile cases of myeloid leukaemia, while preserving a fairly typical blood picture, approximate clinically to cases of acute leukaemia.

189 Fatal Asthma

R. W. LAMSON and E. M. BUTT (*J. Amer. med. Ass.*, May 29, 1937, p. 1843) present a clinical and pathological survey of 187 cases of "fatal asthma." Their findings are noticeably similar to those of an investigation carried out in 1932 on asthma and allied conditions for the Association of Life Insurance Medical Directors. An analysis of the case reports, on 98 of which there was a post-mortem examination, emphasizes an undue predominance of heart and lung disease. Approximately 40 per cent. did not survive four years after showing clinical symptoms, the percentage being even less favourable in females, and the highest mortality occurring at 45 to 55; this result disagrees with the clinical experience of true bronchial asthma. A closer analysis of the unpublished cases on which post-mortem examinations were performed shows that only 26 per cent. could be classified as cases of true bronchial asthma, and that heart and lung disease did not terminate this syndrome. It is difficult to distinguish clinically true bronchial asthma from the other classified types, but in true asthma pathological and microscopical examination of the lungs will show hyperplasia of the bronchiole epithelial lining with mucinous exudates, leucocytic infiltration, and eosinophilia. The writers stress the need for greater caution in employing the term asthma as including such cases as cardiac dyspnoea, tracheal obstruction, and pneumoconiosis, as this reflects unfavourably and inaccurately on the mortality statistics of true clinically recognizable asthma.

190 Tumour of the Right Auricle

A. CLERC *et al.* (*Arch. Mal. Cœur*, June, 1937, p. 361) describe the case of a woman aged 34 who was two months pregnant, and on whom a therapeutic abortion was performed on account of extreme cyanosis and a state of impending asphyxia. The cardiac rhythm was regular and there was no murmur, although there was a vague history of "heart trouble" of considerable duration, and the fingers were clubbed. Following the abortion she had several convulsive attacks, and developed a left hemiplegia, from which she died two weeks later. Necropsy disclosed general congestion of all organs and multiple cerebral haemorrhages. In the right auricle there was a myxomatous "tumour," ovoid in shape and measuring 4 cm. by 3 cm. It projected through the tricuspid valve towards the right ventricle. The authors state that such "tumours" are difficult to diagnose before necropsy, as there are no pathognomonic signs or symptoms. They also discuss the question whether such "tumours" are real neoplasms which have become secondarily vascularized, or whether they are thrombi which have undergone myxomatous degeneration.

191 Benign Bronchial Bleeding

F. FLEISCHNER (*Wien. klin. Wschr.*, June 18, 1937, p. 927) points out that haemoptysis occurs most commonly in pulmonary tuberculosis and bronchial carcinoma and less often in other pulmonary and bronchial conditions, or from laryngeal, pharyngeal, and oral lesions. The author has met with numerous cases of benign haemoptyses of bronchial origin in the past few years. Bleeding occurred while the patient was in good health or after a slight catarrh, and usually while at rest. The blood was bright red, fluid, and not mixed with sputum, and the haemorrhage recurred from time to time. No fever was present either before, during, or after the haemoptysis; and no tubercle bacilli were found in the sputum. Physical examination of the lung was negative, and no lesion could be demonstrated by *x* rays. In nearly all cases some abnormality of the bronchi was present, and calcified glands were found in the neighbourhood. Bronchoscopically the mucous membrane was seen to be granulated, varicose, or eroded. Recognition of this condition will prevent unnecessary or ineffective therapy, though it may also occur in early tuberculosis or bronchiectasis.

Surgery

192 Prolapse of Artificial Anus

F. HOWET (*Scalpel*, Liége, June 5, 1937, p. 720) draws attention to the danger of strangulation which is present when prolapse of an artificial anus occurs. The condition is similar to intestinal intussusception, but of less gravity. Prolapse of the colon is liable to occur when the artificial opening is in the transverse or descending colon, but it is most often seen in the distal segment of a sigmoidal anus. Invagination of the intestine may be slow and progressive, or it may take place within a few hours. In the first instance the eversion of the mucous membrane precedes the prolapse of the wall of the bowel, which it pulls after it. The physiological cause is generally an increase of intra-abdominal pressure due to strain, which may be produced by coughing, anti-peristaltic movements, or atony of the intestinal wall. The length of the mesentery is also a factor to be considered. In order to avoid prolapse it is important that the mesentery should not be too long at the point at which the bowel is brought to the abdominal wall, and also that the incision should avoid injury to the muscles. The wall of the bowel should be fixed to the

parietal peritoneum so that prolapse is impossible. Surgical treatment after prolapse has occurred consists in excising the injured portion of the bowel, careful haemostasis being essential. The mesentery is then shortened and fixed to the peritoneum by sutures, and finally the wall of the bowel is sutured to the skin, the whole operation being performed outside the peritoneum. Two cases are reported, in the first of which the prolapse had not recurred after three years, and the second was also successful but was of more recent date.

193 Primary Tumours of Lymph Glands

T. ANARDI (*Riv. Chir.*, May, 1937, p. 248), after describing the difficulties of classifying primary tumours of lymph glands other than in systemic diseases, divides them into three groups: (1) neoplasms of the parenchyma—lymphoblastoma, lymphocytoma, or lymphoma, according to the degree of cytological development; (2) neoplasms of the stroma—fibroma, lipoma, sarcoma, etc.; and (3) neoplasms of the blood or lymph vessels—endothelioma and perithelioma, to which it appears that the reticuloma (histiocytoma) must now be added. Although the third group is undoubtedly malignant, it is not rare for the growth to be slow, the tumour to remain localized, and for surgical removal, followed by *x*-ray therapy, to effect a cure. Two such cases are reported, one a perithelioma and the other an inguino-crural and a suprahyoid lymph gland endothelioma, which latter was difficult to distinguish from paradental phlegmon. The lymphoglandular perithelioma is rarer than the endothelioma, and seems most common in or near Scarpa's triangle; it may rapidly produce metastases.

194 Recurrent Dislocations of the Shoulder

C. VAN STAVEREN (*Nederl. Tijdschr. Geneesk.*, June 26, 1937, p. 3035) has treated ten cases of chronic dislocation of the shoulder-joint in elderly patients, and obtained good results without operation. In all but one case, in which it was axillary, the dislocation was subcoracoid. The treatment consisted in replacement under an anaesthetic by Cooper's traction method. All the cases were subsequently submitted to *x*-ray examination, and in only one was there any evidence of arthritis deformans.

Therapeutics

195 Pollen Therapy in Hay Fever

D. HARLEY (*J. Path. Bact.*, May, 1937, p. 589) reports a study of the effects of specific pollen therapy on the skin sensitivity as tested by both prick and intradermal methods of forty hay-fever patients who were grass-pollen sensitive. He also made immunological studies of a reaction-inhibiting substance (R.I.S.), which developed in the serum of grass-pollen-sensitive patients after treatment with grass-pollen extract and which inhibited the reaction of non-allergic skins to serum-pollen mixtures. After treatment with grass-pollen extract to a final dose of 100,000 units all the forty patients showed marked reduction in the size of the reactions produced by both prick and intradermal methods. At doses of 20,000 units the prick-test reactions were more greatly reduced than were the intradermal ones. The author concludes, therefore, that a decrease in the size of the specific skin reaction occurs if a sufficiently large dosage of pollen extract is given. Very considerable variations in skin-reactive potency were found in commercial grass-pollen extracts. Using sera from twelve of the patients, it was found that pre-treatment serum mixed with pollen extract failed to prevent a skin reaction in non-allergic test subjects, although at the site of the test pollen extract failed to evoke a reaction twenty-four hours after the first test. On the other hand, when mixed with pollen extract post-treatment serum stopped an immediate reaction but failed to prevent one at the site of the test after an interval of twenty-four hours and also failed to prevent a skin reaction in grass-pollen-sensitive subjects. The R.I.S. thus demonstrated did not destroy or inactivate the idioceptor or the idiotoxin, and appeared to be removed or rendered inactive after twenty-four hours. Anti-pollen precipitin was not found in any of the sera. Further tests showed that the inhibiting effect did not depend on any lengthy interaction between the R.I.S. and the idiotoxin *in vitro*, and suggested that it was the result of an action of the R.I.S. on the idioceptor preventing it from uniting with idiotoxin but not from attaching itself to cells. The interaction between R.I.S. and idioceptor did not appear to be very stable, since the R.I.S. was apparently removed from skin-test sites in twenty-four hours.

196 Antiketogenic Action of Dextrose

According to S. MARKEES (*Klin. Wschr.*, July 10, 1937, p. 985) the antiketogenic action of dextrose seems to be proved by its effects on diabetics and by the perfusion of the excised liver. This effect is more apparent than real; alimentary ketogenesis is not hindered, but ketone-body destruction in the tissues is favoured by the presence of dextrose. Markees has recently shown (*ibid.*, p. 841) that in healthy subjects intraduodenal exhibition of fats leads to their partial β-oxidation in the liver rather than to the transfer to fat depots—a fact which is contrary to expectation and general opinion, especially as glycerin is recognized as an antiketogenic agent. He now finds that in such persons simultaneous or previous administration of dextrose eliminates the resultant hyperketonaemia. That alimentary ketogenesis is preserved, however, is shown by adrenaline-interception tests. Dextrose therefore appears to be antiketogenic only in the sense that it improves the utilization of ketone bodies formed in physiological conditions from fats.

Diseases of Children

197 Pyloric Stenosis

M. KIRSCHNER (*Med. Klinik*, June 11, 1937, p. 785) reviews the present state of the operative treatment of pyloric stenosis in the newborn. He himself performed eighty-nine operations with a mortality of 5.6 per cent., and describes the technique employed. Statistics compiled by Ramstedt show an average mortality of 8.5 per cent., which is about the same as for those treated conservatively. The cases handed over to the surgeon, however, are those in which conservative treatment has failed, and the mortality statistics of the two methods are therefore not comparable. The author stresses the importance of combined surgical and medical treatment. He advises cool wards in the summer, a suitable diet, pre- and post-operative abundant subcutaneous and intravenous injections of liquids, and in grave cases blood transfusion.

198 Skull Fractures in Children

E. SORREL *et al.* (*Presse méd.*, May 22, 1937, p. 761) state that during the last four years they have observed 109 cases of fracture of the skull in children under the age of 15. They were surprised at the high percentage of recoveries even after severe symptoms had been present at the onset, at the speed with which this recovery took place, and at the absence of complications. Accidents in the street or falls from windows or trees were responsible for the majority of the fractures, eighty-six of which took place in children under the age of 10. The extent of the fracture as shown by radiography did not appear to bear any relation to the severity of the symptoms. Two cases are described in which very extensive fractures with haematomata were present; there was an accelerated pulse rate but no neurological signs, and in both instances

the children recovered completely without any after-effects. Meningo-encephalitic complications were fairly common, and there were four cases of extradural haematoma treated by operation. It was thought that this condition was present in other cases which recovered without operation after a period of coma lasting from ten to twenty-five days. There were nine instances of diffuse subdural haemorrhage. The pulse rate was a valuable sign as regards prognosis and treatment. If it rose to between 140 and 180 and then fell slowly, returning to normal in about a week, spontaneous recovery was probable; but if it remained fast, with signs of weakness or irregularity, intervention was usually necessary. Neurological signs, including convulsions, paralysis of the limbs or cranial nerves, hemianopsia, and aphasia, were indications for immediate operative treatment. This was also necessary in open fractures or when grave cerebral lesions were suspected; it was done within forty-eight hours if the pulse rate remained high, and it was carried out in all cases in which a short period of improvement was followed by the reappearance of symptoms. Of the 109 patients under review twenty-four died, nearly all within the first forty-eight hours. There were fifty-three patients who recovered spontaneously, and the remaining thirty-two did so after operation.

199 Osteomyelitis of the Maxilla

According to F. MARTILLOTTI (*Pediatria*, Naples, July, 1937, p. 616) acute osteomyelitis of the upper jaw, although rare, is often present during the first weeks of life. It has then given rise to many diagnostic difficulties and has been called antral empyema, orbital phlegmon, necrotic (dental) folliculitis, and false sinusitis, etc. The settling of a haematogenous infection in a primary dental follicle may be analogous with the common infection of the juxta-epiphyseal line—another region bearing a strain of growth. Martillotti's patient, at the age of 21 days, had had for a week a tender swelling over the left maxilla; *Staphylococcus pyogenes aureus* was found in pure culture in the pus exuding from the left nostril, the left alveolar sulcus, and later the main swelling. There was much tumefaction of the palatal arch on the left, and after twenty-seven days a bony sequestrum was discharged; both these points being against the alternative diagnosis of acute sinusitis, which had to be considered, for although the existence of the sinus at birth has been denied, Della Vedova has found it to be present in the seventh foetal month and to be 10 mm. long at birth. The literature describes numerous fatalities and occasionally sequestral exclusion of dental follicles and severe consequent deformities of dentition. *X*-ray examination is of little diagnostic help in restless and "toxic" infants, and according to Köhler the maxillary sinus is first radiologically distinguishable at the age of from 30 to 36 months. Radical measures have been advised, but Martillotti is satisfied with the excellent result of his conservative treatment, which consisted in local and parenteral exhibition of an autovaccine to the patient and of autovaccination of the nursing mother.

200 Tuberculosis in Children

T. K. WITH (*Acta paediatr.*, Stockh., 1937, **19**, 4, 482) states that the test used in his series of cases was the Mantoux, as he considers that it provides the best reaction for scientific purposes, since it is possible to give the exact doses. The doses varied from 1/1,000,000 mg. to 1 mg., and the varying proportions of redness and infiltration in the reacting area were studied. The sensitivity of the test in various types of tuberculosis was estimated; it was found to be highest in primary tuberculosis and lowest in cases of meningitis and miliary tuberculosis. The graduated intracutaneous test was therefore found to be of value in the routine clinical work of a children's department. In many cases the tests were performed several times during the course of the disease, as well as from six months to one year after the discharge of the patients from the hospital. In only a few cases were variations in sensitivity demonstrated during the disease, but by retesting later it was generally found to be considerably decreased. The proportion of redness and infiltration in this series bore no constant relation to the duration of the infection. A predominance of redness was seen only in a small number of the recent primary infections.

201 G. HERLITZ (*Acta paediatr.*, Stockh., 1937, **19**, Supplement 2) records his observations on 1,457 children of the Swedish working classes, aged from 0 to 15 years. About half reacted to the Pirquet test. The children were examined from five to twenty-three years later, the average time being 13.4 years, and the following conclusions were made. A child with a positive tuberculin reaction but free from any clinical symptoms of tuberculosis runs a greater risk of developing manifest tuberculosis and of dying from it within the next ten to fifteen years than does a child of the same age who responds negatively. In the case of the child with occult tuberculosis this risk outlasts childhood and persists into adolescence. Another conclusion was that it is more dangerous to be infected with tuberculosis during the first two or three decades of life than later on.

202 Pertussis

H. GOLD (*J. Pediat.*, May, 1937, p. 641) records thirty cases of whooping-cough in children aged from 19 months to 7 years who were treated by intramuscular injection of a specific soluble pertussis antigen which was chemically and biologically standardized. Out of twenty-eight cases treated seventeen responded with excellent results and seven with good results. The antigen specifically controlled the paroxysmal stage of pertussis after a few injections, but the treatment had to be continued in order to maintain the relief and to prevent recurrence. The earlier the treatment was given the better were the results.

Obstetrics and Gynaecology

203 Uterus Bicornis Unicollis and Abortion

According to P. CAFFIER (*Zbl. Gynäk.*, July 3, 1937, p. 1575) the uterus bicornis unicollis is often able to carry to term and expel normally a live foetus; it has indeed been confused with pelvic tumour arising in the puerperium, and its true nature has in many cases first been recognized at operation. Either one or both horns may carry successive pregnancies. On the other hand, it is sometimes a cause of habitual abortion, and the symptoms and signs of ectopic pregnancy may be so closely mimicked that laparotomy has on numerous occasions been done for supposed tubal gestation. The case is related of a woman, aged 26, who a year after a third-month abortion again had bleeding and pain after four months' amenorrhoea. From the external os a complete decidual cast, without foetal parts, was removed; a soft right adnexal tumour was regarded as a tubal pregnancy. The patient collapsed, and in preparatory anaesthesia for operation for supposed tubal rupture it was noted that the external bleeding was unusually copious for such a case and that the fundus, now more clearly palpable, was unusually high for ectopic pregnancy. Vaginal examination now showed the foetus projecting from the right gravid cornu into the cervix, and subsequently the left half from which the cast had been taken was identified. A confirmatory hysterosalpingography was carried out. In the prevention of habitual abortion due to uterus bicornis unicollis Caffier advises intensive folliculin therapy with a view to improving the nutrition and functional capacity of the uterus; plastic operation may also eventually be considered. K. HÜBSCHER (ibid., p. 1581)

was led to operate early in a fourth pregnancy with threatened abortion for supposed pelvic tumour or uterine deformity in a patient, aged 25, who had already had three abortions in the third month. He found, in addition to pregnancy in one horn of a uterus bicornis unicollis, a strongly developed retrovesical ligament, representing the remains of the urorectal septum. This was removed, as was also the non-gravid cornu and adnexa of the same side; the pregnancy went on uneventfully to term.

204

Lactation Statistics

P. FELDWEG (*Dtsch. med. Wschr.*, July 2, 1937, p. 1046) reports his observations on 1,352 women confined in a maternity hospital in Pforzheim. It was found that 20.6 per cent. yielded an insufficient supply of milk for their babies, 22.1 per cent. gave a sufficient supply, and 57.3 per cent. had more than enough. In 5.8 per cent. the amount of milk exceeded 800 grammes a day. The high average yield depended largely on the daily pumping of the residual milk after the infant had been fed. With regard to the 20.6 per cent. who did not yield enough, the cause of this insufficiency was only in part due to pathological conditions at birth; it often happened that perfectly healthy mothers who had undergone a normal confinement yielded insufficient milk, whereas mothers whose pregnancies had been complicated by eclampsia or Caesarean section commonly yielded more than was needed. The author assumes that not only in his own hospital but elsewhere in the world at least 50 per cent. of mothers yield more milk than their babies need. In a consecutive series of 242 cases lactation records were kept, after discharge from hospital, of more than 60 per cent. of the mothers who had yielded an ample supply of milk. Only three months after confinement half of these women had ceased to feed their infants, and in only 15 per cent. was the mother's milk the sole source of nourishment. The author traces this deplorable state of affairs to social and psychological rather than to anatomical and physiological factors, the urge to earn money or to play bridge leading in many cases to the cessation of breast feeding. In 1935 there were 86,227 deaths in the first year of life in Germany, and the author traces approximately half of these deaths to disturbances of nutrition due to the lack or inadequacy of breast feeding.

205

Ergobasin

T. ANTOINE (*Wien. klin. Wschr.*, July 2, 1937, p. 999) describes a new alkaloid of secale cornutum, which is marketed under the name of "ergobasin." This is a water-soluble alkaloid of low molecular weight, which has no effect on the autonomous nervous system, but which exercises a specific action on the uterus. It increases the tone of the uterus and gives rise to rhythmic contractions of an increased frequency. It may be given either by the mouth or by injection, and the effect is first observed about five to ten minutes after administration and lasts for six to twelve hours. This drug is useful mainly in assisting the expulsion of the placenta, during the puerperium, and in gynaecological haemorrhages, but it may also be used during the first two stages of labour.

206

Sterility

H. O. NEUMANN (*Med. Klinik*, June 25, 1937, p. 861) relates his experiences with hormone therapy in sterile women. He reports statistics according to which 10 per cent. of marriages in Germany remain sterile, thus reducing by 100,000 the number of births in a year. The author used mainly progynon B oleosum, and obtained variable results. He stresses the fact that there are no contra-indications from the eugenic point of view to the use of hormones in sterility.

Pathology

207

Cholesterin Metabolism

H. BEUMER (*Münch. med. Wschr.*, June 25, 1937, p. 1007) examined the cholesterin metabolism in a boy of 10. The patient was pale and fat; his build was infantile; he suffered from osteoporosis and had xanthomata on his eyelids, elbows, and toes. The liver was enlarged, and the spleen was not palpable. In childhood he had suffered from hypoglycaemic states, which had been relieved by the ingestion of sugar. Acetone was found in the urine. The blood sugar content was 60 mg. per 100 c.cm., and the amount of cholesterin in the serum on admission was 600 mg. per 100 c.cm. While in hospital the patient was given a vegetarian diet consisting of emulsion of almonds, bananas, apples, bread, and potatoes. He was fed for certain periods on food rich in cholesterin, alternating with periods in which the diet contained no fats or cholesterin. It was found that the cholesterin content of the serum was independent of whether the diet was rich or poor in cholesterin, but in cholesterin-poor periods the cholesterin balance was negative, and in the cholesterin-rich periods it was positive. There was no tendency to retention of cholesterin, nor was there any inability to excrete enterogenous cholesterin. The skin symptoms and the enlargement of the liver were not affected by a cholesterin and fat-free diet taken over a period of three months. The author is of the opinion that xanthomata do not depend on alimentary influences, but are due to an endogenous disturbance of the cholesterin metabolism, and that hypercholesterinaemia, which always occurs in simple glycogenesis, is due to endogenous factors.

208

Blood Coagulation by Snake Venom

H. EAGLE (*J. exp. Med.*, May, 1937, p. 613) reports investigations to determine whether the coagulative action of snake venom depends on their enzyme content, and whether it is of two types, one acting on prothrombin to form thrombin, and another acting directly on fibrinogen to form fibrin. Of seventeen venoms tested, nine coagulated citrated plasma, and of these seven coagulated purified fibrinogen. The coagulating action of these seven venoms was independent of calcium ions, tissue or platelet derivatives, and of prothrombin, and was not affected by antithrombin; fibrinogen was therefore attacked directly by these venoms. The optimum *p*H for this reaction was 6.5, the same as that for the action of thrombin on fibrinogen. Of the eleven venoms that did not coagulate fibrinogen, five rendered the protein non-coagulable by thrombin. Both the coagulation and destruction of fibrinogen appeared to be associated with the proteolytic activity of the venom. Five of the seventeen venoms were capable of converting purified prothrombin to thrombin. Of these five, three coagulated fibrinogen but the other two had no effect on it, so that their coagulating power was entirely due to their ability to convert prothrombin to thrombin. The activation of prothrombin by venom occurred in the absence of ionized calcium and of platelet or tissue derivatives, and was prevented by antithrombin; these venoms therefore acted directly on prothrombin. Although the activation of prothrombin took place over a wide range of *p*H, 5.6 to 8.3, the optimum *p*H for the coagulating action of thrombin formed from prothrombin by snake venom was 6.5, the same as for thrombin produced physiologically by calcium and platelets. Nine venoms destroyed prothrombin. Both the activation and destruction of prothrombin appeared to be associated with the proteolytic activity of the venom. There was no apparent correlation between magnitude of proteolytic activity and the type of effect produced on either fibrinogen or prothrombin, and in relation to both fibrinogen and prothrombin there appeared to be two types of enzymes, one destructive and one activating. The relation of the findings to the physiological process of coagulation is discussed.

ONE RESTORATIVE AND FORMATIVE TONIC WHERE TWO WERE NEEDED BEFORE...

MINADEX

Minerals: *Iron, copper and manganese to combat anaemia. Calcium and phosphorus to restore neuro-muscular tone.*

Vitamins: *Vitamin A to maintain the epithelial barrier to infection and to prevent relapse. Vitamin D to ensure assimilation of the calcium-phosphorus.*

An ideal reconstructive tonic for run-down Children . .

Syrup Minadex combines the active principles of two established routine remedies—syrup ferri phosph. co. and cod-liver oil, the vitamins A and D of the latter being incorporated as concentrates free from oil. Clinical experience abundantly confirms the value of Syrup Minadex as a restorative and formative tonic. For infants it can be safely administered in the bottle feed, while its enjoyable flavour ensures that Syrup Minadex is readily taken even by "difficult" children. Always can Minadex be relied upon to produce a dependable restorative effect.

Prices (excepting I.F.S.) 6-oz. bottles, 2 6; 12-oz., 4 6; 80-oz. winchesters, 22 6.

Required together in everyday practice

CALCIUM and VITAMIN D

SPECIAL INDICATIONS ARE:

Capillary effusion and oedema, as in nettle-rash, etc.	*Backwardness in dentition and skeletal development of children.*	*Delayed union of fractures.*
Allergic states.		
Neuro-muscular disorders, as in cramps and tetany.	*Excessive menstrual or post-operative bleeding.*	*To assure adequate calcium reserves for expectant mothers.*

THE varied everyday therapeutic calls for calcium and its necessary complement, vitamin D, emphasise the special value of Ostocalcium Tablets. Each tablet contains 7½ grains of the soluble and diffusible calcium sodium lactate—a clinically adequate quantity—and 500 international units of vitamin D incorporated in the pure crystalline form.

Supplied together in

OSTOCALCIUM TABLETS

Cleavage lines facilitate halving or quartering

Tins of 50, 2/3, 100, 4 -, 500, 12 6, 1,000, 17/6

Less usual professional discount.

G.L. 272

Mild Constipation shown to yield to laxative effect of HOVIS

Many of the mild forms of constipation so prevalent to-day are attributed to the consumption of foods deficient in Vitamin 'B.' In comparing the effects of various kinds of bread it is seen that HOVIS germ bread is superior to either white bread or wholemeal in supplying this deficiency.

Whilst white bread contains practically no Vitamin 'B,' HOVIS, with its added proportion of 25% wheat-germ, supplies an abundance of this essential food-element. Unlike wholemeal bread, HOVIS contains only a minute percentage of bran and indigestible cellulose. In other words its incorporation in the normal diet ensures not only a higher standard of nutrition but easier assimilation and regular evacuation of the intestinal contents.

VITAMIN 'B' CONTENT ACTS AS AID TO REGULARITY

CHRONIC PSORIASIS

Complete cure after local treatment with Peat Ointment.

This letter came to us from a doctor the other week:

Dear Sirs

I am very pleased to report that a young married woman patient has been completely cured of a very long standing Chronic Psoriasis by the use of your Sphagnol Ointment.

I consider that this is very remarkable as this patient has been under treatment for years in private and Hospital, and Sphagnol is the only preparation that has brought lasting relief. Her skin to-day is as soft and clear as in her early childhood days. Needless to say she is extremely grateful and her recovery has caused a great deal of favourable comment.

Yours very truly,
(Signed) M.B., Ch.B., F.R.F.P.S

Though neither dangerous nor painful, psoriasis is still a great annoyance. Usually, correcting faults of clothing and diet will give relief, but sometimes local assistance is necessary. Then regular applications of Sphagnol Ointment, which contains the healing principles of peat, will generally clear up the skin in a very short time.

If you are not familiar with Sphagnol preparations, please let us send you free samples.

Sphagnol

Peat Products (Sphagnol) Ltd., Dept. B.215, 21, Bush Lane, London, E.C.4.

KASENA

THE VEGETABLE LAXATIVE

KASENA is a very pleasant and non-griping aperient prepared by a special process from matured Cascara Bark and selected Senna Leaves. Both are well known and very reliable aperients, and Kasena offers the Physician a trustworthy means of prescribing them when their use is indicated.

KASENA retains the full activity of its constituents and is specially suitable for elderly and delicate persons and for children.

It is invaluable in habitual constipation.

KASENA is supplied in bottles at 1/9, 3/- and 5/6. Postage 6d. extra.

"CERABAN" ADHESIVE SELF-SUPPORTING BANDAGE

The Supplementary or Alternative Treatment to Self-Adhesive Elastic Bandages for

SPRAINS, DISLOCATIONS, CONTUSIONS, SWELLINGS, VARICOSE VEINS, VARICOSE ULCERS, ETC.

Its use eliminates the risk of Dermatitis which so frequently arises from the application of Self-adhesive Bandages.

"CERABAN," whilst free from rubber, possesses elastic properties and when carefully applied to the limb gives substantial support. It is porous, adhesive, and non-irritating, will not chafe and permits of complete respiration of the skin.

In the treatment of Varicose Ulcers the use of "Ceraban" Bandage eliminates the risk of Dermatitis which occasionally occurs through the application of self-adhesive Elastic Bandages. In the less severe of such cases a distinguished authority writing in the *Lancet*, *page 580, Sept. 7th, 1935, issue* recommends the use of "Ceraban." Bandage cut in strips as a first and protective dressing prior to covering with self-adhesive Elastic Bandage and in the more serious cases the complete replacement by "Ceraban." It is waterproof, antiseptic, and being spread on an extensible material readily conforms to the shape of the limb and therefore will not slip.

"THE OMNIPED ELASTIC FOOT CUSHION

is an efficient remedy and a commendable aid to those who suffer from any sort of foot troubles."

States a recent Report from the Berlin Orthopaedic University Clinic.

The Omniped Foot Cushion is a resilient cushion which relieves and supports overstrained muscles without producing the pain which is so frequently inseparable from arch supports and foot correctives. With every step Omniped Foot Cushion automatically massages the muscles, giving them new strength and gradually easing back the whole structure of the foot to its normal position. Letters from Doctors and relieved patients alike are testifying to the success of this valuable new treatment for fallen arches, metatarsal pains, and the various consequent foot troubles. Full information and sample pair will be gladly sent on application.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, and X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, Llantairtechan, amidst the finest scenery in North Wales. On the North-West side of the Estate, a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park. At all the branches of the Hospital there are cricket grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc. For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton), who can be seen in London by appointment

NORTHUMBERLAND HOUSE,

THE RESIDENTIAL TREATMENT OF ALCOHOLIC & DRUG ADDICTION

RENDLESHAM HALL

(Postal Address) — **WOODBRIDGE, SUFFOLK**

RENDLESHAM HALL—SOUTH VIEW

Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

Rendlesham Hall has 45 bedrooms and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated booklet giving particulars as to terms, etc., can be had on application to the

RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: WICKHAM MARKET 16. *(Toll Call from London.)*

Proprietors: The Norwood Sanatorium, Limited

RUTHIN CASTLE, NORTH WALES

The fees are from 15 guineas a week. They include medical attendance, all scientific investigations that may be needed, such as analyses, bacteriological cultures, the ordinary *x*-ray examinations, and electrocardiograph readings; all treatment that may be prescribed such as special diets, insulin, artificial sunlight, electrical treatment, baths, massage nursing; medicines or vaccines, board and lodging.

The only extra charge is that for a complete alimentary *x*-ray examination, or for *x*-ray therapy.

All the usual forms of treatment are given at Ruthin Castle. The climate is mild. The annual rainfall is 30.5 inches, that is, less than the average for England. There is central heating throughout.

Address—THE SECRETARY, Ruthin Castle, North Wales. *Telegrams*—Castle, Ruthin. *Telephone*—Ruthin 66

The University Court will shortly proceed to the appointment of the first CROMBIE-ROSS LECTURER IN PSYCHO-PATHOLOGY.

The appointment is a part-time one.

The salary proposed is £650.

Persons who desire to be considered for the office are requested to lodge their names with the Secretary to the University by September 15th, 1937.

The conditions of appointment may be obtained from the undersigned.

H. J. BUTCHART,
Secretary to the University of Aberdeen.

The University, Aberdeen.

UNIVERSITY OF LONDON

Applications are invited for the WILLIAM JULIUS MICKLE FELLOWSHIP which is of the value of at least £200, and is awarded by the Senate to the man or woman who, being resident in London and a graduate of the University, has, in the opinion of the Senate, done most to advance Medical Art or Science within the preceding five years. Applications must be made before October 1st, 1937. Further particulars should be obtained from the Academic Registrar, University of London, W.C.1.

WESTMINSTER HOSPITAL, Broad Sanctuary, S.W.1.

THE "WANDER" SCHOLARSHIP IN DISEASES OF CHILDREN.

Applications are invited for the office of "WANDER" SCHOLAR (Clinical Pathologist and Registrar to the Children's Department). Salary £250 per annum. Duties to commence October 1st, 1937. Candidates must be registered medical practitioners who have held a resident hospital post and had some experience in pathology or in diseases of children. The office is a whole-time one and is tenable for one year. Applications (six copies), together with six copies of three recent testimonials, should be submitted to the undersigned (from whom further details regarding the duties of the office can be obtained), not later than Friday, September 17th, 1937.

By Order of the House Committee,
CHARLES M POWER, Secretary.

LONDON HOSPITAL MEDICAL COLLEGE.

DEMONSTRATOR OF ANATOMY.

Applications are invited for the appointment of Demonstrator of Anatomy. Salary £400 per annum.

Applications, with copies of three testimonials, will be received by the undersigned up to September 30th.

Turner Street, A. E. CLARK-KENNEDY
London, E.1. Dean.

BOROUGH OF EALING.

DEPUTY MEDICAL OFFICER OF HEALTH.

Applications are invited from duly qualified medical men with a Public Health Qualification for the position of Deputy Medical Officer of Health.

Candidates will be required to carry out medical inspection of school children and child welfare work, and such other work as may be assigned by the Medical Officer of Health.

The person appointed will be required to devote his whole time to the duties, and will not be allowed to engage in private practice. Salary will be at the rate of £750 per annum, rising to £900 by £25 per annum.

A deduction of 5 per cent. will be made from the salary in accordance with the provisions of the Local Government and Other Officers' Superannuation Act, 1922, which has been adopted by the Council, and the appointment will be subject to passing the Council's medical examination in connection therewith. Canvassing will be a disqualification.

Copies of the application form and terms of appointment can be obtained from Dr. THOMAS ORR, Medical Officer of Health, Town Hall, Ealing, W.5, to whom applications, accompanied by copies of not more than three recent testimonials, must be delivered not later than September 30th.

Town Hall, R. H. WANKLYN,
Ealing, W.5. Town Clerk.

WORCESTERSHIRE COUNTY COUNCIL.

ASSISTANT TUBERCULOSIS OFFICER (MALE).

The above-mentioned Council are about to appoint a whole-time Assistant Tuberculosis Officer and applications are now invited for this post.

Applicants must be registered Medical Practitioners between the ages of 25 and 45 years. Special experience and qualifications in Tuberculosis will be necessary, as work under the County Tuberculosis Scheme will form the chief part of the Officer's duties. He should have (1) at least three years' experience in the practice of his profession, (2) spent in general clinical work a period of not less than eighteen months, of which not less than six months have been spent in a Hospital as Resident Officer in charge of beds occupied by general medical or surgical cases, and (3) received special training, for a period of not less than six months, in the diagnosis and treatment of Tuberculosis and in Artificial Pneumothorax treatment. A Diploma in Public Health is desirable. The officer who is appointed will work under the supervision of the Chief Tuberculosis Officer.

The person appointed will be required to reside in the southern half of the County.

The salary will be £600, rising by £25 per annum to £700, with an allowance of £140 per annum for use of his own motor car. The engagement will be subject to three months' notice on either side. The post is designated under the Local Government and Other Officers' Superannuation Act, 1922, and a medical examination will have to be passed by the successful candidate.

Applications (on forms to be obtained from the County Medical Officer, County Buildings, Worcester), accompanied by not more than three recent testimonials, must be received by 15th day of September, 1937, addressed to the County Medical Officer, County Buildings, Worcester.

Canvassing disqualifies, and neither the names of the members of the County Council nor of the Committee will be supplied

(Signed) C. H. BIRD,
Clerk of the County Council.

Shirehall, Worcester.
August 21st, 1937

(J. 133.)

GENERAL POST OFFICE

Headquarters Medical Branch.
(Female Staff.)

There will shortly be two vacancies for ASSISTANT WOMEN MEDICAL OFFICERS in the Headquarters Medical Branch. The appointments will be pensionable and will carry a salary commencing at £500 a year and rising by annual increments of £25 to £700 a year. The rates of salary are liable to review.

Each candidate must be a fully qualified medical practitioner, a natural-born British subject, and the child of a person who is or was at the time of death a British subject. Candidates must also be unmarried or widows. Preference will be given to candidates under 30 who have held one or more hospital appointments. The successful candidate will not be allowed to engage in private practice in addition to their official duties.

Applications, stating qualifications, age, etc., with copies of any recent testimonials, should be sent to the Chief Medical Officer, General Post Office, London, E.C.1, not later than September 20th, 1937.

Political influence should not be sought in support of applications; it would prejudice rather than assist the candidature.

The Female Medical Staff at Headquarters consists of a senior Woman Medical Officer and five Assistant Women Medical Officers. Information as to the duties can be obtained from the Chief Medical Officer.

Candidates may be required to attend for personal interview in London at their own expense.

INDIAN MEDICAL SERVICE

RECRUITMENT OF EUROPEAN OFFICERS

Applications are invited from Medical Men for Permanent Commissions in His Majesty's Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or of £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

British subjects of pure European descent who are under 32 years of age and who are registered under the Medical Acts in force in Great Britain and Northern Ireland are eligible to apply.

CAREERS.

The Indian Medical Service offers a permanent career with wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after one year's Indian Service to have his name registered for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of Civil Officials and for general medical administrative purposes, to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

RATES OF PAY.

Years of Service.	Rank	Basic Pay Rs. per mensem	Overseas Pay. £ per month.	Total £ per annum.

23	"	1350	40	1695
24	"	1500	40	1830
25	"	1500	40	1830

Note.—(1) The rupee is at present stabilized at a rate equivalent to 1s. 6d.
(2) An officer promoted to the rank of Lieut.-Colonel before completion of 20 years' service will receive pay at the rate of Rs. 1200 per mensem (basic) plus £40 per month overseas pay

Extras.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

ANTEDATES IN COMMISSION.

Candidates possessing certain higher medical qualifications or holding the Diploma in Public Health may be granted an antedate in their commissions. Past service in certain hospital appointments may also render candidates eligible for an antedate. Persons holding or about to hold resident posts at recognized hospitals may be seconded in those posts for a period. The maximum period of antedate, secondment, or antedate and secondment combined, admissible under this paragraph, is limited to 18 months.

OUTFIT ALLOWANCE.

Officers on appointment will receive an allowance of £75 towards the cost of outfit.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

LEAVE.

Leave can be taken at reasonable intervals, and adequate rates of leave pay are provided. Extra leave (known as study leave), which may not exceed 12 months in all during an officer's service, may be granted to officers desirous of pursuing special courses of study of a postgraduate nature. During such leave, study allowance, at present fixed at the rate of 12s. a day in the United Kingdom, £1 a day on the Continent of Europe, and £1 10s. a day in the United States of America and Canada is granted to an officer in addition to ordinary rates of leave pay.

PENSIONS.

The rates of pensions are as follows:—

	Per annum.
After 17 years' service for pension	£372 0s.
" 18 " " "	£400 0s.
" 19 " " "	£428 0s.
" 20 " " "	£465 0s.
" 21 " " "	£502 0s.
" 22 " " "	£539 10s
" 23 " " "	£576 10s.
" 24 " " "	£614 0s
" 25 " " "	£651 0s.
" 26 " " "	£697 10s
" 27 " " "	£744 0s.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with free passage to India. The families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges. Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately three months, prior to their embarkation for India on first appointment. Information as to the rates of pay admissible during this period and subsequently up to arrival in India is contained in the memorandum referred to below.

A memorandum giving full details regarding these appointments and forms of application may be obtained from the UNDER-SECRETARY OF STATE FOR INDIA, MILITARY DEPARTMENT, INDIA OFFICE, LONDON, S.W.1. The Selection Committee will meet at the India Office early in October next, and the selected candidates will be required to join a course of instruction commencing about 1st November, prior to sailing for India in February, 1938. Applications should reach the India Office as soon as possible and in no case later than October 2nd.

INDIA OFFICE, SEPTEMBER, 1937

COUNTY COUNCIL OF MIDDLESEX.

The County (Tuberculosis) Sanatorium, Clare Hall, South Mimms, Middlesex.

RESIDENT ASSISTANT MEDICAL OFFICER (male).

Applications are invited for the above appointment. Candidates must be registered medical practitioners, not over 35 years of age, unmarried and of British nationality. They must have held resident hospital appointments. Practical experience in the diagnosis and treatment of tuberculosis will be an additional qualification.

Salary £400 per annum, rising by annual increments of £25 to £475, with board, lodging and laundry, valued at £100 per annum.

The officer appointed will work under the direction of the Medical Superintendent, and devote his whole time to his official duties.

The appointment, which will be subject to medical examination, will be held during the pleasure of the Council, and is terminable by one month's notice on either side.

The appointment, which does not carry any superannuation rights, is for a period of four years, at the end of which period the officer will leave the Council's service. In a special case the Council may decide to retain an officer on the established staff, in which case the salary will be increased to a maximum of £500.

Applications, stating age, qualifications and experience, together with copies of not more than three recent testimonials, must be received by the undersigned not later than September 25th.

Relationship to any member or officer of the Council must be disclosed in the application. Application forms are not provided. Envelopes must be endorsed "Assistant Medical Officer, Clare Hall 'Z'."

Canvassing, directly or indirectly, will be a disqualification.

C. W. RADCLIFFE,
Clerk of the County Council.

Middlesex Guildhall,
Westminster, S.W.1
September 2nd, 1937.

CITY OF BIRMINGHAM

Public Health Department.
Little Bromwich Hospital for Infectious Diseases.

JUNIOR RESIDENT MEDICAL OFFICERS

Two Junior Resident Medical Officers (one male and one female) required. Candidates must be unmarried and must have held previous resident posts in General or Children's Hospitals.

Salary at the rate of £300 per annum, together with board, etc., valued at £150 per annum.

These appointments are limited to twelve months. The officers appointed will be required to pay to the Council all fees, allowances, and emoluments (other than the foregoing) received by them.

It is not feasible to attend classes for the D.P.H. in conjunction with these appointments.

Forms of application may be obtained from the Medical Superintendent, Dr. J. McGarrity, Little Bromwich Hospital, Birmingham, 9, and should be returned to him on or before September 18th.

The Council House, F. H. C. WILTSHIRE,
Birmingham. Town Clerk.

Aug 1st 30th, 1937 Cardiff.

BOROUGH OF WILLESDEN.

RESIDENT MEDICAL OFFICER

Applications are invited for the post of Resident Medical Officer at the Willesden Municipal (Fever) Hospital. The salary will be at the rate of £250 per annum with board, lodging and laundry, and the appointment is for a period of twelve months. The Hospital admits all the notifiable diseases.

Applications, stating age, qualifications and previous experience, with copies of three recent testimonials, to be sent to the Medical Superintendent, Willesden Municipal Hospital, Brentfield Road, Neasden, N.W.10.

E. A. PRATT,
Town Clerk.

September 6th, 1937

COUNTY OF DORSET.

Assistant County Medical Officer and Medical Officer of Health for the Wareham Borough, the Wareham and Purbeck Rural District, and the Swanage Urban District.

The Dorset County Council invite applications for the joint whole-time appointment of ASSISTANT COUNTY MEDICAL OFFICER AND MEDICAL OFFICER OF HEALTH for the Wareham Borough, Wareham and Purbeck Rural District, and Swanage Urban District (population about 25,000).

The salary for the combined appointment will be £800 per annum, together with a travelling allowance of £80 per annum and necessary out-of-pocket expenses according to the scales now in force.

Applicants must be qualified in accordance with Article 8 of the Sanitary Officers (outside London) Regulations, 1935, and hold the Diploma in Public Health or similar qualification.

The candidate appointed will, as regards his duties as Assistant County Medical Officer, act under the direction of the County Medical Officer of Health, and will be required to perform such duties as may be from time to time prescribed. As regards his duties as Medical Officer of Health, he will be subject to the control and direction of the District Councils concerned.

The post will be designated under the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination. He will also be required to reside within the area for which he is Medical Officer of Health and to take up his appointment on January 1st, 1938.

Candidates must apply in their own handwriting on the prescribed form, to be obtained, on receipt of a stamped addressed foolscap envelope, from the undersigned, by whom applications, accompanied by copies of not more than three recent testimonials, must be received not later than Monday, September 20th, 1937.

Canvassing in any form will be a disqualification.

County Offices, C. P. BRUTTON,
Dorchester. Clerk of the County Council.
August 21st, 1937.

LANCASHIRE COUNTY COUNCIL.

JUNIOR ASSISTANT MEDICAL OFFICER.

Wrightington Hospital, Appley Bridge.

Applications are invited for the post of Junior Assistant Medical Officer (male, unmarried) for the Wrightington Hospital, which contains 206 beds for non-pulmonary tuberculosis (adults and children) and 20 beds for "combined" pulmonary and non-pulmonary cases. Salary £200 per annum, together with board, residence and laundry.

The appointment will commence on October 1st or thereabouts, and will be for 12 months.

The medical staff consists of medical superintendent, two assistants, two consultant orthopaedic surgeons and other visiting surgeons. There are excellent facilities for reading for M.D.

Forms of application and conditions of appointment obtainable from Central Tuberculosis Officer, County Offices, Preston. Letters to be marked "Wrightington M.O."

Closing date September 17th, 1937.

County Offices, GEORGE ETHERTON,
Preston. Clerk of the County Council

THE CHRISTIE HOSPITAL AND HOLT RADIUM INSTITUTE, WITHINGTON, MANCHESTER, 20.

Applications are invited for the post of RESIDENT MEDICAL OFFICER to the above Hospital and Institute for duty with the Radiotherapy Department. Appointment is for six months in the first instance, but is renewable.

Salary at the rate of £150 per annum, plus residence (private suite), board, etc.

The appointment offers an excellent opportunity of obtaining experience in Radium and X-ray Therapy. Candidates must have had previous Medical and Surgical experience.

Applications, stating age, qualifications and previous experience, to be submitted immediately to the undersigned

PERCY N. GLASS,
Superintendent.

CITY AND COUNTY OF NEWCASTLE-UPON-TYNE.

NEWCASTLE GENERAL HOSPITAL (800 Beds.)

ONE SURGICAL REGISTRAR (PART-TIME)

Applications are invited from duly qualified and registered Medical Practitioners for the above post.

The salary in respect of the appointment is £250 per annum.

Further particulars may be obtained from the Medical Officer of Health, Health Department, Town Hall, Newcastle-upon-Tyne, 1, to whom applications, accompanied by not more than three recent testimonials, should be delivered on or before September 18th, 1937.

August 27th, 1937.

COUNTY BOROUGH OF MERTHYR TYDFIL.

APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited from medical women (unmarried or widowed), under the age of 40, for the above post. The person appointed must be a registered Medical Practitioner, and registered in the *Medical Register* as the holder of a Diploma in Sanitary Science, Public Health, or State Medicine. Preference will be given to a candidate who:

1. has had at least three years' experience in the practice of her profession;
2. has held the appointment of Resident Medical Officer in a Maternity Department for a period of not less than six months;
3. has had not less than one year's continuous experience in some branch of obstetric work.

The duties will include School Medical Inspection; Supervision of Midwives; attendance at Ante-Natal and Infant Welfare Centres; and other Public Health duties as may from time to time be prescribed. The duties of the respective offices will be carried out under the general direction of the Medical Officer of Health.

The commencing salary will be at the rate of £500 per annum, rising by annual increments of £25 to a maximum of £700 per annum.

Applications, together with copies of three recent testimonials, must reach the undersigned on or before September 16th, 1937.

Town Hall, T. H. STEPHENS,
Merthyr Tydfil. Medical Officer of Health.
August 30th, 1937.

LEIGH JOINT HOSPITAL BOARD.

Applications are invited from Medical Men (under 45 years of age) for appointment as MEDICAL SUPERINTENDENT of the BOARD'S INFECTIOUS DISEASES HOSPITAL, situate at Astley.

The salary assigned to the office is at the rate of £800 per annum, together with the usual residential allowances.

He will be required to reside in the residence provided (unfurnished) by the Board.

The post is designated under the Local Government and Other Officers' Superannuation Act, 1922, and the emoluments for the purpose of the Act are valued at £150.

Preference will be given to applicants who have held resident medical appointments, since qualification, at an Infectious Diseases Hospital and are experienced bacteriologists.

The appointment will be terminable by one month's notice on either side.

Forms of application may be obtained from, and must be returned when duly completed to, the undersigned by noon on Thursday, September 16th, next.

Canvassing, either directly or indirectly, will disqualify.

The Sanatorium, ERNEST WILIAMS,
Astley, Nr. Manchester. Clerk to the Board
August 22nd, 1937.

CITY OF BIRMINGHAM

PUBLIC ASSISTANCE COMMITTEE.

ERDINGTON HOUSE

ASSISTANT RESIDENT MEDICAL OFFICER

The Public Assistance Committee invite applications from fully qualified medical practitioners for appointment as Assistant Resident Medical Officer at Erdington House.

The Institution, which is approved for the purposes of the D.P.M. has accommodation for upwards of 1,800 inmates and is set apart for the reception of all classes of mental and nervous disorder. The admission rate is 1,500 per annum.

Parts of the Institution are certified under the provisions of the Mental Deficiency Acts, 1913/1927. There are facilities for research on the pathological and biological side, and the appointment gives opportunities for postgraduate study.

The Officer appointed will be required to assist in the general medical work of the Institution under the supervision of the Senior Medical Officers. Four weeks' leave of absence will be granted to the successful candidate during the term of office.

The appointment will be for a period of twelve months, and the salary attached to the appointment will be at the rate of £300 per annum, together with full residential emoluments (rations, apartments, laundry, and attendance).

The appointment will be subject to one month's notice on either side.

Any further particulars as to the Institution and/or duties may be obtained upon application to the Medical Officer of the Institution, Dr. H. F. Kirkland, to whom applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, should be forwarded so as to reach him not later than 10 a.m. on Wednesday, September 16th, 1937.

Canvassing in any form, oral or written, direct or indirect, will be regarded as a disqualification.

Council House, F. H. C. WILTSHIRE,
Birmingham, 1. Town Clerk
August 26th, 1937

LONDON COUNTY COUNCIL.

PUBLIC HEALTH DEPARTMENT.

Applications are invited for two vacant positions of PART-TIME OBSTETRICIAN AND GYNAECOLOGIST. Appointments will be to the hospital service of the Council, but in the first instance one of the appointed officers will be allocated to DULWICH and ST. GILES' (Camberwell) Hospitals and the other to ST. MARY, ISLINGTON, ARCHWAY (Highgate) and HIGHGATE Hospitals. Remuneration £800 a year and £600 a year respectively. Each officer will be responsible, subject to the general administrative supervision and control of the medical superintendents, for the whole of the obstetric and gynaecological work at the hospitals to which he is attached (there are no maternity beds at Archway and Highgate Hospitals). Each officer will be required to live within a reasonable distance of these hospitals and to visit them daily and as required (weekly and as required in the case of Archway and Highgate Hospitals).

Application forms containing further particulars (stamped addressed envelope necessary) from the Medical Officer of Health (S.D.6), County Hall, Westminster Bridge, S.E.1. Forms returnable by September 24th. Canvassing disqualifies.

LONDON COUNTY COUNCIL.

INFECTIOUS HOSPITALS.

Applications invited from medical practitioners for appointment as ASSISTANT MEDICAL OFFICERS (Grades I and II) at various hospitals for infectious diseases. Salaries are:—Grade I, £350-£25-£425 a year; Grade II, £250 a year, both inclusive of board, lodging and washing. Candidates for Grade I positions should have had experience in a resident appointment in a general hospital, and must have had fever experience. Appointment as assistant medical officers, Grade II, are for one year only in first instance (renewable for a second year under certain conditions), but officers are eligible for promotion to Grade I after a minimum period of six months' service.

Application forms obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health (Staff Division 2), County Hall, S.E.1, returnable by September 15th. Canvassing disqualifies.

LONDON COUNTY COUNCIL.

Applications invited from Medical Practitioners with appropriate qualifications for the appointment of ASSISTANT PATHOLOGIST in the Council's pathological service. Salary £650-£25-£800.

For appointments in the Group Laboratories candidates should have special experience in one or more branches of pathology in relation to the diagnosis and treatment of disease.

For the appointment at the Central Histological Laboratory advanced experience in morbid histology and post-mortem work is essential.

Forms of application and further particulars (stamped addressed foolscap envelope necessary) from Medical Officer of Health (Staff Division 2), County Hall, Westminster Bridge, S.E.1, returnable by September 24th, 1937.

Canvassing disqualifies.

LONDON COUNTY COUNCIL.

ASSISTANT MEDICAL OFFICER (man or woman) required for mental services. Candidates (under 35 years of age) must (I) be registered to practise both in medicine and surgery in England; (II) be of at least one year's professional standing; and (III) have held residential position in general hospital for six months, or comparable general experience. Salary £470 a year, rising by £25 to £570 (additional allowance of £50 to holders of D.P.M.) No emoluments. Charges for board, lodging, etc. (at present £2 9s a week) if required to be resident. Pensionable. In the case of women, marriage terminates contract of service.

Application form, returnable by September 22nd, obtainable from Chief Officer (B), Mental Hospitals Department, Shell Mex House, Strand, W.C.2. Canvassing disqualifies.

COUNTY BOROUGH OF WEST HAM. PLAISTOW FEVER HOSPITAL. (210 Beds.)

Applications are invited for the post of JUNIOR ASSISTANT MEDICAL OFFICER (male) at the Plaistow Fever Hospital.

Salary £300 per annum, together with residence, board and laundry. The appointment is for one year.

Preference will be given to candidates who have held a resident appointment in a general hospital. Good facilities for post-graduate study are available.

Application forms can be obtained from the Medical Officer of Health, Municipal Health Offices, Romford Road, Stratford, E.15, and should be returned, together with copies of not more than three recent testimonials, to the Town Clerk, Town Hall, West Ham, E.15, not later than September 20th.

HULL CORPORATION HEALTH DEPARTMENT.

ASSISTANT MEDICAL OFFICER OF HEALTH FOR PORT SANITARY WORK.

Applications are invited from duly qualified medical men, under the age of 40 years and of not less than three years' standing in their profession, for the appointment of an ASSISTANT MEDICAL OFFICER OF HEALTH, at a salary of £660 per annum, rising by annual increments of £25 to £700 per annum.

Candidates must hold a registered degree or diploma in State Medicine or Public Health.

The person appointed will be engaged primarily on routine Port Sanitary Work, Medical Inspection of Aliens, Bacteriological Work, and the Control of Infectious Diseases, but may be called upon to do work in any other department of the Public Health Services in accordance with the Corporation's scheme for the interchange of medical staff.

Experience in Port Sanitary Work and Infectious Diseases will be considered important qualifications for the appointment.

The appointment may be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Applications, on forms to be obtained from the undersigned, with copies of not more than three recent testimonials, are returnable not later than noon on Thursday, September 23rd, 1937.

Health Department. NICOLAS GEBBIE, M.D.,
Guildhall, Hull. Medical Officer of Health.
September, 1937.

PALMERSTON NORTH HOSPITAL, NEW ZEALAND.

RESIDENT MEDICAL OFFICER AND REGISTRAR.

Applications are invited for the post of Resident Medical Officer and Registrar at the above Hospital.

Salary £450 per annum.

Applicants should be single. The appointee will be required to live in. The duties of the position, apart from the medical registry work, include supervision of medical wards and supervision of outpatients.

Further details may be obtained from the Office of the High Commissioner for New Zealand, New Zealand Government Offices, 415, Strand, London, W.C.2.

Applications to furnish a detailed statement as to age, qualifications and experience, and to be accompanied by copies only of testimonials, close with the undersigned on October 30th, 1937.

A. J. PHILLIPPS,
Managing Secretary.

COUNTY BOROUGH OF BRIGHTON.

BRIGHTON MUNICIPAL HOSPITAL.

THIRD RESIDENT ASSISTANT MEDICAL OFFICER (male).

Applications are invited for the above post at the Brighton Municipal Hospital, which is a General Hospital containing 620 beds.

Salary £300 per annum, with board, residence and laundry provided.

The appointment is a whole-time one, and will be for a period of one year.

Candidates must have held a house physician's appointment at a recognized hospital, and preference will be given to those who, in addition, have had practical experience of anaesthetics and maternity work.

The candidate must be single.

The post is designated under the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination before being appointed to the position.

Particulars and forms of application can be had from the undersigned.

Latest date for receipt of applications September 27th 1937.

IAS. H. ROTHWELL,
September, 1937. *Town Clerk.*

HOUNSLOW HOSPITAL, HOUNSLOW, MIDDLESEX.

APPOINTMENT OF RESIDENT MEDICAL OFFICER.

Applications are invited from registered medical practitioners (male) for:—

R.M.O. Salary £250 per annum, with full board, etc., and extras of approximately £150-£200 per annum. Previous Hospital experience essential. Appointment for an initial term of six months, with possibility of further extensions.

Applications, stating age, nationality, qualifications, and previous experience, together with copies of three recent testimonials, must reach the Secretary by Thursday September 23rd, endorsed "Appointment."

HORACE W. CARPENTER,
Secretary.

COUNTY BOROUGH OF SMETHWICK.

SENIOR ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER.

The Council invite applications from qualified medical men for the combined post of Senior Assistant Medical Officer of Health and Assistant School Medical Officer. The officer will rank next in seniority to the Deputy Medical Officer of Health.

The salary will be at the rate of £650 per annum, rising by £25 per annum to a maximum of £800 per annum. The officer will be required to reside at the Isolation Hospital, and a deduction of £150 per annum will be made in respect of board, residence and laundry.

The officer appointed will work under the general supervision and control of the Medical Officer of Health and School Medical Officer, and will be required to render assistance in the general work of the department. The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the selected candidate will be required to pass a medical examination.

Forms of application may be obtained from the Medical Officer of Health, Public Health Department, Hales Lane, Smethwick, to whom application endorsed "Senior Assistant Medical Officer of Health and School Medical Officer," and accompanied by copies of three recent testimonials, must be delivered not later than first post on September 25th, 1937.

Canvassing, directly or indirectly, will disqualify.

Council House, FRANK CHAPMAN,
Smethwick. Town Clerk.
September 6th, 1937.

CITY OF MANCHESTER.

MONSALL HOSPITAL FOR INFECTIOUS DISEASES. (600 Beds.)

APPOINTMENT OF TWO RESIDENT ASSISTANT MEDICAL OFFICERS.

The Public Health Committee invites applications from registered medical men for the post of Resident Junior Assistant Medical Officer (grade 2) at the Monsall Hospital.

Preference will be given to applicants who have held resident surgical and medical posts in a general hospital, and have taken the diploma in Public Health, or have special experience in bacteriology, and who have had previous experience in fevers.

The salary for the appointments is £250 per annum with board, residence and laundry in addition, subject to the Manchester Corporation conditions of service.

The appointments will be made in the first instance for a period of six months, renewable for a further six months, but not renewable thereafter.

Full information and forms of application may be obtained from the Medical Officer of Health, Sunlight House, Quay Street, Manchester, 3, and applications for the post must be received by him not later than September 25th, 1937.

F. E. WARBRECK HOWELL,
TOWN CLERK.

Town Hall, Manchester, 3.
September 6th, 1937.

HOSPITAL OF ST. CROSS, RUGBY. (120 Beds.)

WEEKLY, PRICE 1/3, No. 4002

In Pernicious and Post-operative Anæmias . . .

A palatable liquid extract of hog's stomach containing *Hæmopoietin* in stable solution.

The stomachs are treated immediately after killing to extract the *Antianæmic Factor* in active condition producing a bland liquid of pleasant flavour—HOGASTRIN.

A dose of two teaspoonfuls in a little water three times a day for a fortnight, then reduced to one teaspoonful, will invariably give good results in the treatment of all *Macrocytic Anæmias.*

Packed in 4 oz., 8 oz. and 16 oz. bottles.

HOGASTRIN

For inspection sample and literature apply to the manufacturers:—

GILES, SCHACHT & CO.
Clifton, Bristol, 8.
Manufacturing chemists for over a century.

YES

YOU CAN SAFELY PRESCRIBE THIS TEA FOR ALL YOUR PATIENTS

Not because it is specially prepared in any way whatever, but simply because it is harmless to the most delicate digestion. The Doctor's China Tea is a blend of the choicest teas that China grows—teas which contain comparatively so little tannin that they can be enjoyed by all. For over a quarter of a century The Doctor's China Tea has been recommended by the medical profession—even in cases of dyspepsia and gastritis. A generous free sample will be sent to any doctor who would like an opportunity of trying the tea.

THE DOCTOR'S CHINA TEA

Priced at 2/10, 3/4, 4/-, and a super quality at 4/6 per lb.

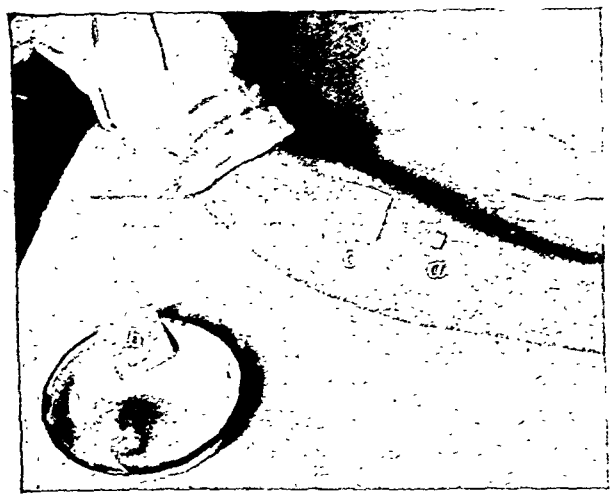
Prescribe healthier food and cool kitchens



Doctors constantly prescribe diets and tend the health of the population, but much less frequently have knowledge of how the food of the patient is cooked, yet the value and wholesomeness of food depends greatly on how it is prepared. The advantage of electric cookers in this respect is obvious. The food is cooked in absolute immunity from the noxious fumes of combustion. A joint, electrically cooked, cannot absorb impurities because there are none in an electric oven. It loses much less weight and succulence in the cooking, which is specially important in families with small incomes. Electrically prepared food is also generally better cooked, as heat can be regulated with precision. Being fumeless and dustless and needing no laying or stoking, electric fires make for much healthier conditions in the kitchen and much less work for the housewife. Electric fires are not the privilege of the well-to-do. Thousands of working class families use them in modern dwellings. Thousands more would do so if they realised the value to themselves

For further information apply to the British Electrical Development Association, 2 Savoy Hill, London, W.C.2, or consult your local Electricity Authority

TUFT'S Clinical ALLERGY

An Entirely New Book

Technique of patch test: (a) small square of blotting paper (or linen) upon which liquid to be tested is dropped; (b) square of adhesive with cellophane on under surface to protect liquid; (c) final patch placed in position on patient's arm.

DR. TUFT'S *new* book is a *practical, down-to-the-minute,* and, above all, *clinical* discussion that provides a wealth of sound advice on the successful diagnosis and treatment of Allergic conditions. It is based on clinical experience—planned and systematically organized to give both the practitioner and the specialist exactly the kind of help that they want. Dr. Tuft considers in detail serum, drug, food, pollen, bacterial and physical allergy, giving causes, symptoms, means of recognizing each type and the therapeutic measures indicated. He devotes *105 pages* to an excellent discussion of *Asthma* and its Treatment. He gives full chapters on Allergic Rhinitis, Hay Fever, Gastro-Intestinal Allergy and Migraine. He includes an entire section on Allergic Dermatoses and 'Allergy' in Relation to the Specialties, with a whole chapter on Allergy in Children. He explains terminology and sets down the general principles of diagnosis and treatment. He details the technique and use of new and standard tests. Laboratory methods, household materials and foods and the possible allergens they contain, allergens and their sources, technique of oral desensitization, allergic diets and recipes, physical exercises for the asthmatic patient and directions for asthmatic and hay fever patients are all thoroughly covered in the Appendix.

CONTENTS of this NEW Book

Terminology and Anaphylaxis

Allergy in Man

Diagnosis, *including examination and tests*

Treatment, *including symptomatic treatment, drug therapy, prophylaxis*

Ætiologic Types, *including full chapters on serum, drug, food, pollen, bacterial and physical allergy*

Asthma, *covering 105 pages with full details of diagnosis and treatment*

Allergic Rhinitis, *including causes, pathology, symptoms, diagnosis and treatment*

Hay Fever, *including causes, diagnosis and treatment*

Gastro-Intestinal Allergy

Migraine, *including exciting factors, types, diagnosis and treatment*

Allergic Dermatoses

Urticarial Dermatoses *(Hives, Angioneurotic Œdema, Erythema Multiforme, Purpura, etc.)*

Atopic Dermatitis *(Atopic Eczema or Neurodermatitis)*

Contact Dermatitis *(Allergic Dermatitis of the Contact type, Dermatitis Venenata)*

Allergy in Children

Allergy in Relation to the Other Specialties

Appendix, *including Laboratory Methods, Diets, etc.*

Octavo of 711 pages, illustrated. By LOUIS TUFT, M.D., Chief of Clinic of Allergy and Applied Immunology, Temple University Hospital. Introduction by JOHN A. KOLMER, M.D., Dr.P.H., D.Sc., LL.D., L.H.D., Professor of Medicine, Temple University. Cloth, 36s. net.

MAW STEROTHERM

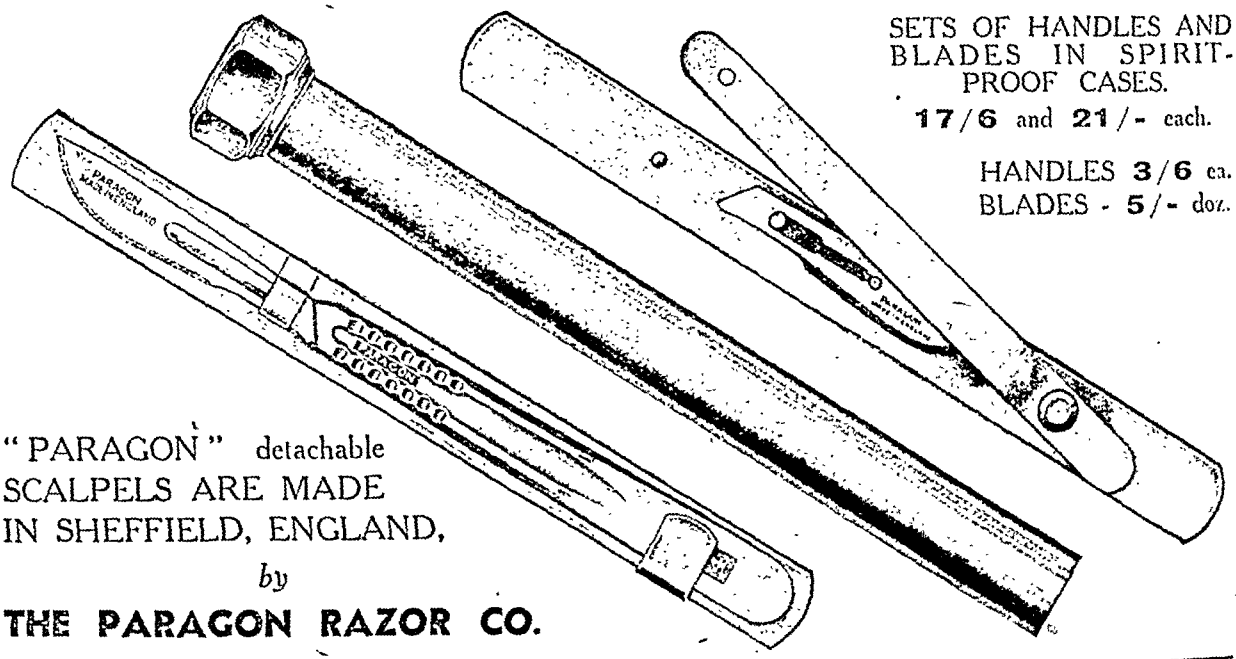
HOT AIR ELECTRIC AUTOMATIC STERILIZER

Patent No. 427581

Maw Sterotherm Automatic Sterilizers have been installed in the London, Westminster and many other Hospitals, Surgeries, etc., throughout the country and are functioning with the utmost efficiency. The special features of the Sterotherm ensure complete sterilization of Instruments, Dressings, Oils, etc., by the Hot Air method. It is the ideal unit where economy of space and outlay are essential.

May we send you details or arrange a demonstration?

SPECIAL FEATURES



- Efficient Sterilization.
- Automatic regulation of temperature.
- No supervision necessary while in use.
- Very small current consumption.
- Articles in apparatus remain sterile until required, as closure is bacteria proof.
- Dressings quite dry after leaving Sterilizer.
- Convenient size—length 16½ in., diameter 9½ in.

Salt and Son Ltd.

SALT'S PATENT KIDNEY BELT

Each of these Belts is made to the individual measurements of its ultimate wearer. As a result one can confidently expect really efficient support for displaced or floating kidney. Comfortable pressure *under* the kidney effectually prevents that organ from dropping. Symptoms due to dragging on the renal ligaments are obviated, while the danger of hydronephrosis, produced by kinking of the ureter, is considerably diminished. A special pamphlet on "Movable Kidney," together with Salt's Corset and Belt Book, can be had post free on request by interested Medical Men.

'CELLANBAND'

ANTISEPTIC PASTE-IMPREGNATED

BANDAGES

The CELLANBAND Dressing, when properly applied, furnishes a mechanical support vastly superior to crepe or rubber bandages, elastic hosiery, etc., and will usually be found sufficiently robust to enable the convalescent to resume reasonable light duties at an earlier period. CELLANBAND Dressings exercise a marked dehydrating and antiphlogistic effect, resulting in rapid reduction of oedema. Air-access to the tissues is not interfered with as in the case of gelatine dressings, so that evaporation of the skin secretions continues normally.

12/- PER DOZ. (7 yds. long, 4 in. wide)
SAMPLE BANDAGE **1/-** POST FREE

'SANOID'

STERILIZED LIGATURES

These ligatures are British both in production and materials. Their Tensile strength is well in excess of the recognised standards for particular sizes. A special process gives a surface-finish that ensures easy manipulation. SANOID Ligatures are exceedingly supple; the catgut straightens out and remains straight without "kinks" which are liable to cause breakage. Sterilization is carried out by the most up-to-date methods, and independent Bacteriological tests over several months in all cases gave negative results. Exceptional elasticity lessens the risk of necrosis.

THYMINIC ACID BASE

URALYSOL

TRADE MARK

FORMULA

Thyminic Acid	0·10
Hexamethylenetetramine Anhydromethylenecitrate	0·50
Hexamethylene Tetramine	2·50
Piperazine Tartrate ..	0·25
Lithium Carbonate ..	1·00
Sodium Benzoate ..	1·00
Effervescent Base ..	ad 100

DIRECTIONS

One teaspoonful to be taken morning and night in a tumblerful of water.

Uralysol, in addition to being a solvent and eliminator of pathological Uric Acid, is a powerful urinary antiseptic.

Normally there exists in the body a certain quantity of uric acid, which assists general metabolism, and after it has played its part is eliminated together with the normal thyminic acid of the organism. When, however, uric acid is present in excess, the body needs additional thyminic acid to supplement the resultant deficit of this normal solvent of uric acid.

Uralysol, by its thyminic acid content, supplies the agent necessary to dissolve excessive uric acid.

The next step is the elimination of this thyminic-uric acid which, being in excess of normal, necessitates treatment by an agent capable of enhancing elimination.

Uralysol, by its content of hexamethylenetetramine and lysidin, stimulates the organism to eliminate the pathological uric acid already dissolved by its thyminic acid content.

Samples and literature on request.

QUESTIONS and ANSWERS

Doctors have asked many questions concerning Dole Hawaiian Pineapple Juice since this natural unsweetened beverage was introduced to Britain. We are always pleased to answer questions personally, but for your convenience we have listed those asked most frequently.

1 *Is it a by-product? What do you add to it? Water? Sugar?*
It's far from being a by-product. The juice is extracted from sun-ripened Dole-grown Hawaiian pineapples. The exclusive Dole Fast-Seal Vacuum-Packing Process brings it to you field-fresh, with no added sugar, no preservatives.

2 *Where can I buy it?*
At nearly all grocers.

3 *Is it good for babies?*
Yes, it's an item of infant diets in many hospitals. It is easily digested and assimilated. Here's a typical analysis of Dole Pineapple Juice.

Moisture	85.3%
Ash	0.4
Fat (ether extract)	0.3
Protein (N×6.25)	0.3
Crude fibre	0.02
Titratable acidity as citric acid	0.9
Reducing sugars as invert sugar	12.4
Carbohydrates other than sugars (by difference)	0.38

GLUCO-FEDRIN

THE development of vehicles suitable for medicaments employed in the treatment of inflammation of the nasal mucosa has been the subject of special investigation. Studies in the Parke-Davis Laboratories have been undertaken with the specific purpose of finding a vehicle that is stable, non-irritating and miscible with the nasal secretion. Various oils and oily emulsions were discarded because, being immiscible, they tended to hinder or delay the action of medicaments. Aqueous solutions and glycerinated vehicles are not entirely free from irritating properties. An isotonic dextrose solution containing menthol, Chloretone and ephedrine was found to be superior to other preparations tested. Its blandness, ready miscibility with the nasal secretion, and stability make it particularly satisfactory. Such a combination is now available under the name "Gluco-Fedrin" and is suggested for use as a vaso-constrictor in diagnostic investigations of the nose and accessory sinuses as well as for the treatment of hayfever and other forms of allergic rhinitis.

Supplied in 10 c.c. bottles, each with a dropper.

FORMULA

Ephedrine ..... 1 *per cent.*
Chloretone ... 0·5 *per cent.*
Menthol ..... 0·1 *per cent.*
Dextrose Solution ..... *q.s.*

For the patient who is depressed

For the treatment of debility or depression, whether accompanied by some form of anæmia or simply persisting as a result of the patient being 'below par' through exigencies of daily life or suffering from lack of tone following illness, Livogen by reason of its content of the Vitamin B complex, hæmoglobin and extract of liver provides a ready means of overcoming the particular dysfunction. A physician reporting on its use states :—

'. . . *I have noted the remarkable tonic-properties in most of the patients to whom I have prescribed Livogen. It increases vitality, overcomes lowered resistance and banishes the feeling of depression.*'

——— M.D.

Livogen is readily taken even by fastidious people and by some who are acutely ill; it is particularly acceptable if taken in iced water or soda water. Livogen is perfectly harmless, and excessive dosage even to children is followed by no ill-effects.

THE 'BETWEEN-MEAL SNACK' —ITS EFFECT ON WORKING EFFICIENCY

How Cadburys Milk Chocolate provides nourishment in a convenient form

THE conventional spacing of meals — 3 per day with a considerable gap in between them — has by recent research been shown not to give the uniform energy output which is desirable. In many normal people working efficiency drops considerably before their next meal is due. In such cases a small between-meal snack will be found most beneficial. The merits of milk in this connection are well known, but conditions of work are not usually favourable to anything save the most compact and portable form of nourishment. It is here that the advantages of Cadburys Milk Chocolate become apparent — supplying as it does all the goodness of milk in a concentrated and convenient form.

That in conversion the nutriment and food values of the milk are not modified or decreased is demonstrated by a vitamin assay of Cadburys Milk Chocolate made by the highest independent authority. The chocolate was found to contain 6 International Units of Vitamin A per gram as compared with a stated potency for milk of 3 International Units per gram.

1½ glasses of full-cream milk contained in every ½lb. block

Oral Vaccine for the prevention of Colds and Influenza

Since Genora brand Oral Vaccine was introduced to the Medical Profession last Winter, extensive clinical and laboratory tests have shown that it establishes a high degree of immunity against colds and influenza; the oral vaccine has also proved successful in the treatment of chronic bronchitis and similar respiratory infections.

This vaccine contains hæmolytic streptococci, in addition to other organisms incriminated in the causation of coryza and influenzal infections. It has been found that the ingestion of the oral vaccine against colds and influenza also develops immunity to diseases caused by hæmolytic streptococci.

Particulars concerning Genora brand Oral Vaccine will be found in the new brochure on Vaccine Therapy which has recently been published by Genatosan Ltd. This booklet also gives information regarding a wide range of vaccines administered by hypodermic injection and the standard types of Local Immunity Products. A copy of the brochure will gladly be supplied to any physician on request.

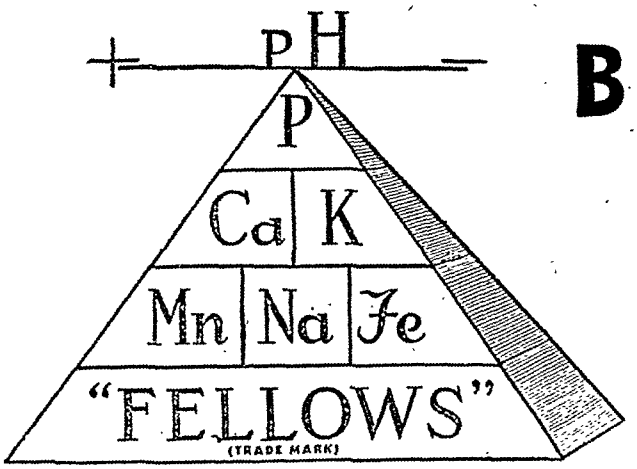
COD LIVER OIL

is the only Liver Oil with a pedigree of proved achievement behind it

. . now available in a PALATABLE, HIGH-POTENCY FORM

The study of Vitamins A and D originated through research into the value of Cod Liver Oil as a builder of constitution—sufficient proof of its long standing as a nutritive food. Cod Liver Oil contains nature's Vitamins A and D in their right proportion. That is why it is specifically recommended by the Ministry of Health and the League of Nations Nutrition Committee. Only its general character has been against it in the past but now we have got over this difficulty. We have produced in "SevenSeaS," for the first time, a Cod Liver Oil of fresh pleasant flavour in high potency form.



"SevenSeaS" is obtainable in three forms: (1) High Potency Oil—four times B.P. standard; (2) High Potency Capsules containing 5 mm. dose of High Potency Oil; (3) Standard B.P. Oil. We would like all practitioners to prove "SevenSeaS" High Potency Cod Liver Oil to their own satisfaction. Please send to the address below for a free sample.

PRICES:

HIGH POTENCY OIL (*you only need 5 drops*) - 1/3 *bottle*
HIGH POTENCY CAPSULES (25 *Capsules*) - 1 6 „

Cystopurin

The ideal biliary antiseptic

1 Produces no irritation or toxic effects.

2 Is readily absorbed.

3 Is active in either an acid or alkaline medium.

4 Renders the bile bactericidal and sterilises infected bile and the biliary passage.

5 Acts on causative organisms which may reach the biliary system through the systemic circulation and the alimentary tract.

6 Acts as a prophylactic.

7 Promotes biliary drainage.

8 Is perfectly safe, even in large doses.

CHOLECYSTITIS

From information received:—

"I wish to state that the patient with cholecystitis to whom I administered Cystopurin has recovered."

"Cystopurin worked well in cure of cholecystitis and cleared up all symptoms and tenderness. There is no doubt it is good and far easier to take and absorb than any similar preparation."

"Oral administration of Cystopurin was shown to be preferable to —— and within 15 days of the commencement of daily treatment, the organisms entirely disappeared. ——, administered for a similar period, whilst freeing the urinary system of organisms, failed to influence the infection of the gall bladder and bile, which remained positive."

Supplied in bulk and in tubes of 20 tablets for dispensing purposes.

A SOLUTION TO AN AGE-OLD PROBLEM

'When purgatives are conveyed to the stomach and are there dissolved, they are carried by the same passages as the food; and when they cannot be digested but their prevailing power remains unsubdued, they return and carry with them whatever opposes them; and this is called purging.'

Aristotle. Problem 43.
(Quoted by Paul of Aegina)
384-322 B.C.

The abuse of purgatives was fully understood centuries ago, but the medicaments available were limited in number. The treatment of constipation was a difficult problem.

Constipation may now be treated in the modern way by the use of 'Petrolagar,' which, by mixing intimately with the intestinal contents, provides a soft faecal mass which is easily evacuated by normal peristalsis. 'Petrolagar' emulsion also has an emollient soothing action on inflamed mucous areas and for this reason is invaluable where spastic bowel or colitis is present.

'Petrolagar' is extremely pleasant to take and may be diluted with water, milk or fruit juice if desired. For the convenience of the medical profession it is dispensed in four varieties:

1. Plain
2. With Phenolphthalein
3. Alkaline
4. With Cascara

"COMMON COLD"
AND
ANTI-CATARRH VACCINE (EVANS)
(LOCAL STRAINS)

For Prophylaxis and Treatment

The facilities of the pathological laboratories at **EVANS' BIOLOGICAL INSTITUTE** enable us to issue vaccines prepared from organisms collected in the locality in which the vaccine is to be used. It will be appreciated that such vaccines are highly specific, producing a greater porportion of successful results compared with ordinary Stock Vaccines.

The following formulæ have been evolved, after many years experience, as having a comprehensive selection of organisms as found in numbers of typical cases, in the correct proportions.

"COMMON COLD" & ANTI-CATARRH VACCINE (EVANS)
(No. 3, for Prophylaxis)

M. catarrhalis	200	million
Diplococci pneumoniæ	200	,,
Streptococci	200	,,
B. Friedlander	100	,,
B. septi	100	,,
Staphylococci (alb. et aur.)	200	,,
M. tetragoni	100	,,
B. influenzæ	100	,,

per cc.

"COMMON COLD" & ANTI-CATARRH VACCINE (EVANS)
(No. 1, for Treatment)

M. catarrhalis	50	million
Diplococci pneumoniæ	50	,,
Streptococci	50	,,
B. Friedlander	25	,,
B. septi	25	,,
Staphylococci (alb. et aur.)	50	,,
M. tetragoni	25	,,
B. influenzæ	25	,,

per cc.

DOSAGE—PROPHYLACTIC (Vaccine No. 3)

As different patients vary in their reaction to vaccine treatment, it is only possible to suggest the average procedure. A brochure which deals fully with the question of dosage will be sent on application. In general, a series of three injections (given before the season during which the person is usually susceptible) is recommended. The initial dose is 0.25 cc. followed by 0.5 cc. after an interval of seven days, and a further 1 cc. after another week or so.

DOSAGE—CURATIVE (Vaccine No. 1)

In acute conditions an initial dose of 0.1 cc. or 0.2 cc. and in chronic conditions 0.25 cc. The initial dose may be repeated after three days. If no reaction is produced, subsequent injections can be larger.

EVANS' "COMMON COLD" AND ANTI-CATARRH VACCINES (Local Strains) are issued as follows:

Boxes of 3 × 1 cc. Ampoules, No. 3 Vaccine (Prophylaxis) .. 7/6 per box
Boxes of 6 × 1 cc. Ampoules, No. 1 Vaccine (Treatment) .. 14/- per box

Also in 5 cc., 10 cc. and 25 cc. bottles and in single Ampoules

A STUDY OF DIET IN RELATION TO HEALTH

DARK ADAPTATION AS AN INDEX OF ADEQUATE VITAMIN A INTAKE

TECHNIQUE AND PRELIMINARY RESULTS

BY

J. R. MUTCH, M.D., D.O.M.S.

AND

H. D. GRIFFITH, B.A.

(Under the supervision of Sir J. B. Orr, M.D., F.R.S., Rowett Research Institute, Aberdeen)

The power that the eye has of accommodating itself to alterations in illumination is called adaptation. When an individual comes out of bright sunlight into a dimly illuminated room surrounding objects at first are invisible; as adaptation takes place first the general outline and then details of surrounding objects can be clearly seen. The time necessary for adaptation was first measured by Aubert in 1865, and since then has been studied by many observers. The sensitivity of the retina to light increases rapidly during the first ten minutes, a much slower but gradual increase taking place up to forty minutes. At the end of that time the retinal sensitivity to light has increased several thousand times. When a person leaves a darkened room and enters bright sunshine a feeling of dazzle is experienced. Rapid adaptation, however, takes place, sensitivity being enormously reduced in twenty seconds (Adams, 1929; Lythgoe, 1926). Failure of adaptation in reduced light is known as night-blindness, hemeralopia, or nyctalopia.

Association with Vitamin A

The association of night-blindness with diet is not the result of recent advances in knowledge of vitamins, but was accepted and quite extensively studied before vitamins were known or any theory could be advanced as to the nature of the relationship. Defective dark adaptation has always been common among poor people living chiefly on plant foods. Liver has been used as a cure since 1500 B.C., and was recommended for this purpose by Hippocrates (Aykroyd, 1930; Tansley, 1931). The frequent discussion of the defect during the last century shows that it must have been common throughout Europe. The peak of incidence seems to have been during the Lenten fasts in the Danubian and Eastern Mediterranean countries and in Russia. After the description by Bitot in 1863 of xerosis conjunctivae combined with hemeralopia, Netter pointed out that night-blindness can occur without xerosis, and it became evident later that the two are stages in the same disease process, night-blindness coming first (Fridericia and Holm, 1925).

Towards the end of the century Lohmann (1913) wrote: "Malnutrition is the cause of the frequent hemeralopia which occurs in poorhouses and orphan asylums. . . ." "Hemeralopia is rare in England but common in Ireland. . . ." It is clear that it must have been common in England also, earlier in the century at least, since in the report of the medical officer of the Privy Council for 1862, where the health of the unemployed Lancashire cotton operatives is discussed, the passage occurs: "Ulceration of the cornea was inquired for but was only heard of *with special prevalence* . . ." in certain areas. It must therefore have been common at all times, and it would certainly have been preceded and accompanied by night-blindness. (See also Berry, 1886; Forbes, 1811; Snell, 1876; Spicer, 1892.) After the discovery of visual purple it was suggested that this pigment was responsible for vision in low illuminations, a theory which was supported by the demonstration of the bleaching of visual purple in light and the restoration of its colour in darkness. Finally, after the discovery of vitamin A and of its relation to xerophthalmia, experimental study of the eyes of rats showed that in vitamin A deficiency, before xerosis of the conjunctiva is obvious, the restoration of visual purple after bleaching is delayed (Fridericia and Holm, 1925; Holm, 1925). At this stage clinical hemeralopia in the rats was demonstrated by simple tests in a dimly lit room in which the rats had to jump from the corner of a table to reach a shelf of cages.

Practical Aspects

With the rapid improvement in diet in this country since the beginning of the century obvious deficiency diseases, including xerophthalmia, have become more and more uncommon, and interest centres at present on the question of the extent to which further improvements are required. Since the important dietary sources of vitamin A—milk, butter, eggs, liver, carrots, and green vegetables—are, on the whole, relatively expensive foodstuffs, it may be predicted that deficiency, if it is found at all, will be more common among the poorer people. The general conditions of life in this country are not such as to reveal deficient dark adaptation. In towns no one is called upon to do work or get about in light less than adequate even for inefficient dark vision, and even in the country such inefficiency of vision might be completely unnoticed. On the other hand, in certain occupations, particularly motor driving and aviation, efficient visual adaptation to low illuminations and to sudden changes in light intensity is of the greatest importance. A high proportion of flying accidents occur at night, and of

motoring accidents at twilight. Delayed dark adaptation is probably of importance also with reference to dazzling by strong head-lamps (Jeghers, 1937). The problem is therefore not of merely academic interest.

Glare has long been regarded as an important factor in the production of night-blindness. The classical instances are the Brazilian labourers who could see when setting out to work before sunrise but not when returning in the evening in better light (de Gouvea, 1883); the soldiers who became night-blind after a parade in bright sunshine or the painter after painting a white façade (Lohmann, 1913); and the sailors in tropical regions (Forbes, 1811) or the fishermen in Newfoundland or Labrador who go night-blind in the summer unless they drink cod-liver oil (Aykroyd, 1930). These cases afford a clinical parallel to the experimental production of hemeralopia in the rats, to which reference has been made. Since the effect of exposure to bright light in cases of vitamin A deficiency is evidently cumulative and may become severe, it does not appear advisable to use in testing capacity for adaptation any experimental procedure which involves frequent or prolonged bleaching of the visual purple.

Present Investigation

The results to be presented now are preliminary to a study of diet in relation to health which has been begun in Aberdeen and will be carried out at other centres in Scotland and England. Methods similar to those adopted here and other more elaborate methods are in use at many research centres in Denmark, Belgium, the United States, and elsewhere (Edmund and Clemmesen, 1936; Jeans *et al.*, 1937; Jeans and Zentmire, 1934, 1936) for the purpose of discovering the extent to which deficiency of vitamin A exists and the daily requirements of vitamin A to ensure perfect health. It is not suggested that the amount which may be shown to be necessary to ensure the maximum possible efficiency of visual adaptation will necessarily be optimal for all functions, but it can be stated that the requirement for perfect health cannot be less than the amount needed to ensure perfect dark vision.

Assuming that a method has been found which will accurately measure the power of adaptation, the following main questions arise: (1) to what extent do differences in the power of adaptation occur; (2) can adaptation be improved by giving vitamin A; (3) is defective adaptation associated with habitual low intake of vitamin A; (4) is it possible to state with any degree of certainty what regular intake is required to maintain maximal power of adaptation. Only the first two questions will be discussed in this paper. As the investigation proceeds, data will be presented relating to the other two.

Description of Apparatus

Since the test was intended for use chiefly with children and a large series of observations was contemplated, it was necessary to have a method that would be simple and yet accurate, and, as it was proposed to examine children at different centres, the apparatus had to be self-contained and of such a size that it could be easily transported.

The test consists essentially in measuring the power of distinction under different illuminations. White cards devised by Edmund (1936) were used. They have printed on them the letter E in different shades, varying from a letter printed in black to one on which faint grey can just be distinguished against the white background. In the series of nine cards the "contrast" of the letter against the unprinted background decreases in geometrical progression. The "contrast" is measured by the difference between the diffuse reflecting powers of the unprinted and printed parts of the test card, divided by the reflecting power of the unprinted part, and for the successive cards of the series has the following values:

$$^1/_{10^0};\ ^1/_{10^{0.25}};\ ^1/_{10^{0.50}};\ ^1/_{10^{0.75}};\ ^1/_{10^{1.00}};\ ^1/_{10^{1.25}};\ ^1/_{10^{1.50}};\ ^1/_{10^{1.75}};\ ^1/_{10^{2.00}}.$$

To designate the individual cards the logarithms of the reciprocals of these fractions are used, so that the black letter on the white background corresponds to 0.00 and the faintest letter on the white background is designated 2.00: on this card the grey is so faint that its reflecting power is 99 per cent. of that of the white background. The letter is 63 mm. high; the breadth of the limbs 12 mm. This is slightly larger than the 6/36 letter on a Snellen chart. As the card is placed at a distance of about 40 cm. from the eye, the visual angle is large, so that even in very low illuminations where there is a physiological central scotoma, the letter can still be distinguished. To vary the apparent brightness, Tscherning's photometric glasses are used. These glasses are of a neutral grey tint and are so constructed that they absorb light after a logarithmic scale, No. 1 glasses transmitting 1/10 of the incident light, No. 2 glasses $1/10^2$, No. 8 glasses $1/10^8$. The two 60-watt lamps used give an illumination on the card of 1,670 metre-candles. When the cards are viewed through the series of Tscherning glasses the apparent illumination is reduced, as in the following table:

Tscherning Glass No.	1	2	3	4	5	6	7	8
Apparent illumination in metre-candles	167	16.7	1.67	0.167	0.0167	0.00167	0.000167	0.0000167

Since this investigation had to begin on a certain date to fit in with other clinical studies, there was not sufficient time to measure the illumination used before starting the clinical work. After the apparatus had been in use for some time it was suspected that the illumination was higher than that used by Edmund (1936), since several subjects were found who could see card 0.50 through the No. 8 glass. Later, physical measurement showed that the illumination was 1,670 metre-candles (8.22 Tscherning) instead of 1,000 metre-candles (8.00 Tscherning) as used by Edmund. Our curves may therefore be expected to be displaced to the right by 0.22 Tscherning relative to those given by Edmund.

ILLUMINATION OF TEST CARDS

The illumination of the test cards was determined as 1,670 metre-candles by comparison with a surface illuminated by a standard 10 candle-power Vernon Harcourt pentane lamp, using a photo-electric cell as a transfer instrument. A copper/copper-oxide photo-electric cell was fitted with a neutral grey glass filter of transmission coefficient 2.07 per cent. (1/48.2). Exposure of the combination of cell and filter in the plane occupied by the test type gave a deflection of 26.7 cm. on a moderately sensitive galvanometer connected to the cell. The cell, without the filter, was then exposed at 54 cm. distance from the pentane lamp (with appropriate diaphragms to eliminate scattered light), and a galvanometer deflection of 26.4 cm. was observed. The intensity of illumination of the test type was therefore:

$$\frac{10}{0.54^2} \times \frac{26.7}{26.4} \times 48.2 = 1{,}670 \text{ metre-candles or lux.}$$

Conversion to the Tscherning scale of brightness may be made to an adequate approximation by assuming that 1,000 lux corresponds to Tscherning 8. The illumination of the test cards would therefore be $(\log_{10} 1670 + 5) = 8.22$

Tscherning; or if a reflecting power of 75 per cent. is assumed for the white card the brightness will be 8.09 Tscherning.

EFFECT OF FLUCTUATION OF SUPPLY VOLTAGE DURING TESTS

Fears that fluctuation of the voltage of the electric supply might vitiate the results by causing serious variation in the illumination of the test cards were found to be without foundation. Observations extending over several days with a self-recording galvanometer connected to the photo-electric cell showed that the maximum variation of illumination amounted to ± 15 per cent. (voltage variation ± 5 per cent.): during the forenoon hours, when most of the tests were done, the variation was only ± 7 per cent., or ± 0.03 Tscherning. Apparatus for control of input voltage was therefore unnecessary for the purpose of the tests. The details of construction of the test-cabinet are shown diagrammatically (Figs. 1, 2, 3, and 4).

Test type	3	1	3
Import duty		13	0
Tscherning photometric glasses (small) ...	6	16	6
Import duty	3	8	3
Box: material and cost of making ...	3	10	8
Total	£17	9	8

Test type from Nyrop and Maag A/S., Copenhagen; Tscherning photometric glasses from Guilbert, Routit et Cie, 114, Rue du Temple, Paris (III); box: home made.

FIGS. 1, 2, 3, and 4.

The cabinet is 19 inches long, 13 inches deep, and 19 inches high. The lettering is as follows:

A: a light-tight box;
B: carrier for the Tscherning glasses (C);
D: wooden holder for the lens carrier;
E: brass eyepiece;
F: wooden tube;
G: Card carrier to hold two cards, sliding in the runners (H); while one card (K) is opposite the opening (J) another card (K^1) can be fitted into the carrier and when the first card (K) is recognized by the patient the carrier is pushed along, causing the second card (K^1) to come opposite the opening (J);
I: two racks to hold the series of cards;
L: two 60-watt translucent electric globes.

Technique

The test is performed in a dark room. Card 0.00 is placed in the carrier G, the card being then opposite the opening J. Card 0.25 is fixed in the other space in the carrier. The slide is pushed along until glass 8 is opposite the eyepiece. The nature of the test is carefully explained to the subject. The cards with the letter E are shown, and the subject is made to understand clearly that no other letter will be shown, and he is required only to say in what direction the E is pointing. Only children capable of doing this have been tested so far. Before beginning the test the subject is kept in the dark room for at least fifteen minutes. If the position of the E is correctly given for the 0.00 card the slide is pushed across so that the 0.25 card is now opposite the opening. When the subject fails to distinguish the direction, the Tscherning glasses holder is pushed along, and glass 7 comes opposite the eyepiece. The subject is then looking at the card that he just failed to see through the darker glass. This procedure is continued until a card value has been found for each of the Tscherning glasses. The values so found can then be shown in graph form. Illustrative examples are given below.

Time Allowed for the Eye to Become Dark Adapted.—The time taken for ten normal individuals to see card 0.00 through glass 8 was as follows:

4 individuals saw card 0.00 through glass 8 in 5 minutes.
4 " " " " 7 "
1 " " " " 10 "
1 " " " " 12 "

Twenty normal individuals were kept in darkness for times varying from fifteen to sixty minutes. No appreciable difference could be found in the adaptation curves of these individuals. It can therefore be stated that if an individual be dark-adapted for fifteen minutes the adaptation will be approximately at its upper limit for that individual.

Time Taken to Complete the Test.—The time taken by 100 individuals to complete the test varied from seven to fifteen minutes. By prolonging the test in repeat examinations no higher values could be obtained. About ten minutes for the complete test is, in most cases, adequate.

Factors which may Influence the Test

Pathological eye conditions, such as retinitis pigmentosa and chronic glaucoma, which are known to cause night-blindness were excluded from this investigation. All patients received a complete ophthalmological examination, and only those that had normal visual acuity were examined for dark adaptation. Several of the children wore glasses. This did not appear to have any influence upon the adaptation curve.

Practice was another factor which might have influenced the test. The essentials of the test were clearly demonstrated before actual testing was begun. The method is so simple and easily understood that children of 6 years of age with normal intelligence had no difficulty in understanding what was required. A slight improvement only was found in the adaptation curve of university students upon repeating the examination a week later under similar conditions (Table I; Fig. 5). When a similar experiment

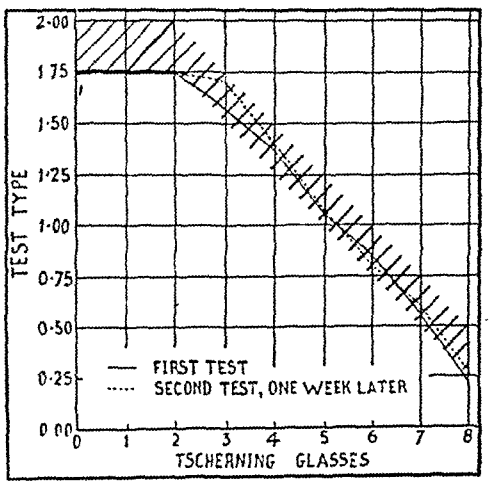

FIG. 5.—Effect of practice on ten university students. The shaded zone represents the upper and lower limits of normal adaptation.

was performed upon seven East End school children a negligible improvement was noted through glass 7 only. This improvement could quite easily be accounted for by the fact that these children were examined on the two occasions on the same forenoon and kept in the dark from the beginning of the first until the end of the second test. The first test was started on the first subject ten minutes after entering the dark room, and an even greater improvement in the adaptation curve might have been expected from increase in dark adaptation. It can therefore be stated that in our experience practice has little or no influence on the accuracy of the test.

Normal Power of Distinction

The individuals who have been examined number 130. The majority of them have been tested twice; about fifty have been examined three or four times. These preliminary studies include ten university students, twenty mill girls, twenty industrial school boys, and twenty-three children of employed and unemployed working-class

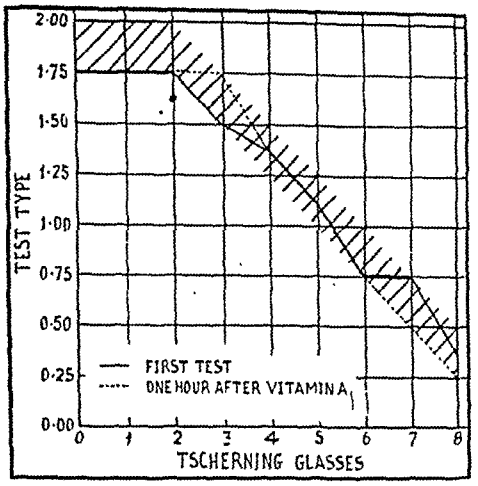

FIG. 6.—Effect of 16,000 units of vitamin A on two university students. The shaded zone represents the upper and lower limits of normal adaptation.

parents, for whom the average results are shown in the tables and graphs. After completion of the first test a single dose of 16,000 units of vitamin A, as halibut-liver oil,* was given to two of the university students and to all of the other subjects, and a second test made one hour afterwards. It will be seen that little improvement fol-

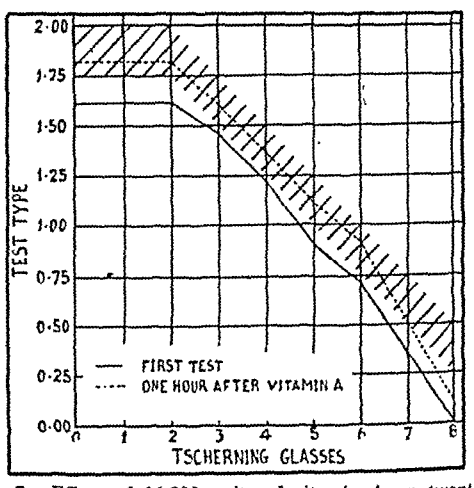

FIG. 7.—Effect of 16,000 units of vitamin A on twenty mill workers. The shaded zone represents the upper and lower limits of normal adaptation.

lowed the taking of vitamin A in the case of the university students (Fig. 6), but a definite improvement occurred in all other cases (Figs. 7 and 8). A similar dose of vitamin A was given on each working day and each school day for a fortnight to those of the mill workers who gave unusually poor first curves and to the elementary school children. The mill girls showed a dramatic improvement at the end of the fortnight, but the elementary school children little improvement beyond that produced by the single dose, except at the two ends of the scale, where

* The capsules of halibut-liver oil used were kindly supplied, without charge, by Messrs. Crookes, to whom we express our thanks. Stated value, 8,000 international units per capsule.

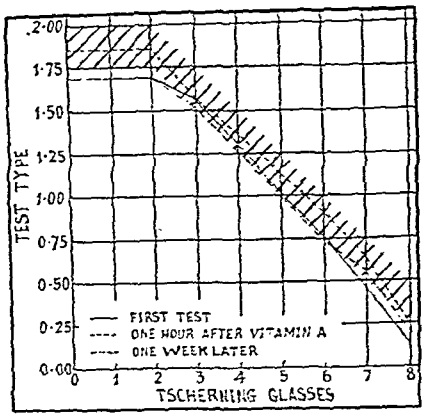

FIG. 8.—Effect of vitamin A on twenty industrial schoolboys. The shaded zone represents the upper and lower limits of normal adaptation.

the improvement was definite (Fig. 9). On testing these children again, a fortnight after stopping the vitamin A, a slight decrease in adaptation was found, but not to the level of the first test.

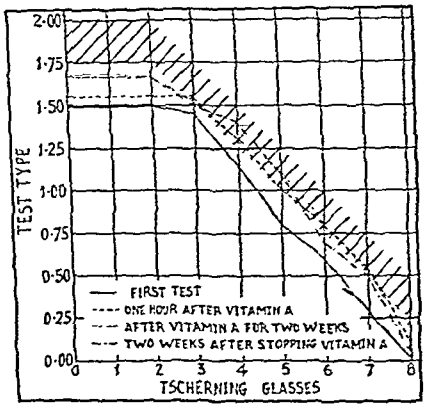

FIG. 9.—Effect of vitamin A on twenty-three working-class children. The shaded zone represents the upper and lower limits of normal adaptation.

It may therefore be tentatively suggested that the performance of the university students—and of other adults of similar class, tested but not here recorded, who gave similar results—is such as to be unaffected by increase in vitamin A intake, and is therefore optimal. A large proportion of the other subjects did not attain this standard, and these, without exception, improved after administration of vitamin A. On the basis of these results it appears that any subject giving an initial curve below the following may be expected to respond to vitamin A:

Tscherning Glass No. ..	8	7	6	5	4	3	2
Test card	0.25	0.50	0.75	1.00	1.25	1.50	1.75

It also appears that the most perfect curve that can be expected will be:

Tscherning Glass No. ..	8	7	6	5	4	3	2
Test card	0.50	0.75	1.00	1.25	1.50	1.75	2.00

These limits are represented in the graphs by the shaded area.

A point that may be of practical importance is that administration of vitamin A very definitely affects not only the vision at minimum illumination (glasses 8 and 7) but also the power of distinction at an illumination equivalent approximately to twilight (glass 4), and even at the highest illumination and in daylight.

TABLE I.—*Ten university students, aged from 18 to 21 years*

Test	Tscherning Glass No. ..	8	7	6	5	4	3	2

D	" "	0.05	0.50	0.70	1.10	1.40	1.50	1.66

A, first test; B, one hour after 16,000 units vitamin A; C, vitamin A for two weeks; D, two weeks later.

Summary

The estimation of power of dark adaptation by means of Edmund's hemeralopia test type and Tscherning photometric glass is described and preliminary results presented.

A limit is shown below which all subjects react with improved adaptation to administration of vitamin A.

whose first performance is above this limit give no response to vitamin A.

The test is sufficiently simple to be applied to intelligent children of 6 years, so short that it is suitable for serial examinations, and the results are unaffected by practice.

We have pleasure in acknowledging the co-operation of Dr. I. Leitch and Mr. D. Lubbock in organizing and carrying through this investigation.

MODERN METHODS OF TREATMENT OF CLUB-FOOT*

BY

DENIS BROWNE, F.R.C.S.

Surgeon, Hospital for Sick Children, Great Ormond Street

It is very flattering but slightly uncomfortable for one who is not an orthopaedic surgeon to be invited to open a discussion at an orthopaedic meeting. However, in the present interesting but undeveloped state of surgery it is probably useful for someone to work at right angles to the accepted lines of specialization, limiting his cases by their age rather than by the system of the body that is affected. So, taking advantage of my position as an amateur orthopaedist, I will start with the platitude that before beginning to treat a condition it is of advantage to decide what that condition actually is. In the case of talipes I believe that this can be done.

The Cause of Talipes

The teaching at present is that the cause of talipes is unknown. I believe, on the contrary, that it is possible to establish beyond doubt the existence of a definite category of congenital deformities due to mechanical causes, and that the classical "talipes equino-varus" is the middle range of a certain series of these deformities. It has been an interesting task working out the limits and possibilities of this category, and I have given elsewhere a summary of the evidence I have collected on the subject (1936). The result has been to convince me that these congenital deformities of the feet are only understood in all their degrees of severity and all their complications and variations when looked at in this light; and that this understanding is a not entirely negligible help to their treatment.

It is interesting to examine the causes that prevent the general recognition of what I believe to be an important and definite pathological category. First among the difficulties comes the complication of the argument. Even to state it properly would be a long day's work, and no one could possibly imagine a busy surgeon devoting a day to listening to it. No journal would publish such a statement except in a form compressed to the verge of unintelligibility; a book on the subject might have a sale of a dozen copies; and meetings of this sort are in their hurry a poor substitute for the leisurely courts of argument of the mediaeval schoolmen.

Then the mental process employed is one that is almost entirely neglected in medicine. We have become used to depending on the fruitful and valuable experimental method, in which we produce artificially certain happenings, observe them, and draw conclusions. But there is another method used in science. No one can play experiments on the planets, but yet we know a good deal about them. We have learnt it by reasoning out what would happen were a certain hypothesis true, and comparing these results of abstract thought with what actually does happen.

It is on this second plan that I have tried to investigate the group of congenital deformities to which I consider talipes to belong; and it is because of its unfamiliarity in medicine that very few of my colleagues seem to see the line of argument or admit its strength. The reason for using it is that it is notoriously difficult to interfere in the processes of gestation without wrecking it. I can think of certain experiments that would confirm my results, but to me they appear simply unnecessary cruelty. And, after all, the Chinese have done some fairly relevant experiments on the female human foot. Shortly, the argument is that if one works out in the abstract what would be the consequences of certain things going wrong in the delicate correlation between the growing foetus and its expanding surroundings, one can deduce a series of deformities exactly duplicated over a period of years in the outpatient department of any children's hospital.

Certain stock objections to this theory are made, usually with a kind of hint that the objector could easily think of more, and stronger ones, if it were worth his while. They all seem to me to show a failure to grasp what the hypothesis attacked actually is. For instance, Middleton (1934) says that the negative is proved once for all by the occurrence of talipes in foetuses 3 months old. I believe that compression can begin its work when the foetus is two millimetres long. Burns and Ellis (1937), remarking that there are many cogent arguments against it, give as a sample of them that in the early days of pregnancy the foetus can move freely within the uterus. I have been unable to find any work illuminating this point, but granted the freedom of movement to be as great as it is usually thought to be, this freedom seems a curious argument against the possibility of displacement. And, anyhow, it is no part of the hypothesis that the displaced feet have ever been in normal position; the probability is all the other way. If any one really wants to attack my hypothesis, here are some of the main lines of argument which have to be explained away.

1. The position of the normal foetus before birth.—I believe the drawings of the foetus in textbooks of obstetrics to be inaccurate in certain very important points.

2. The position and range of movement of the feet in the newborn infant.

3. The occurrence of "pressure dimples"; a most interesting line of argument.—Their variations according to degrees of pressure, and normal or abnormal positions of the limbs, seem

* Read in opening a discussion in the Section of Orthopaedics, including Treatment of Fractures, at the Annual Meeting of the British Medical Association, Belfast, 1937.

to me to be a conclusive proof of the argument. And finally there is their absence in arthrogryposis, a condition I believe to be due to increased hydraulic pressure.

4. Mutual deformities, where two deformed parts that have been pressed together fit into each other like the die and the coin stamped by it.

5. The correspondence of shape of the feet with the position of the joints of the legs, in the different types of talipes.—A variation on this argument is the difference between the feet in double talipes, which I believe to be due to compression (not necessarily abnormally high compression) in a cross-legged position. The invariable difference between the degree of deformity in the feet is just what would correspond to the greater pressure on the outer leg.

6. The variation of the states of the joints and muscles with the degree of pressure as shown by the severity of the deformity and the extent of the dimpling.—The compression theory does not call for any new pathological process of spontaneous muscular degeneration to explain this; it merely assumes that the tissues affected behave as they are known to behave after birth in similar circumstances of pressure and immobility.

7. The much greater frequency and severity of moulding of the feet as compared with moulding of the hands.—This would be expected, as the feet are so much less sheltered.

8. The very complicated but to me satisfactory explanation of arthrogryposis in terms of hydraulic pressure, with its strong confirmation from a disease of sheep.

9. A new confirmation from brain surgery that I have just thought of.—In that syndrome of lumbar spina bifida and talipes which I believe to arise from pressure before the spinal cord has formed, it is well known that hydrocephalus very often occurs. All the cases which develop it have a peculiar deformity of the medulla and upper part of the spinal cord, exactly as if the brain had been squeezed out of the foramen magnum like tooth-paste out of a tube (Russell and Donald 1935). This interferes with the circulation of the cerebro-spinal fluid, and so causes hydrocephalus. It is hardly necessary to point out that, given mechanical pressure on the foetal skull, one would expect this very effect.

Treatment

MANIPULATION

It is curious how much of the present surgical practice can be upset by a simple statement of the aims of treatment. If one states the platitude that one is trying to obtain the normal range of movement of an infant's foot it means that the talipes foot is not corrected until it will go up with the slightest pressure into full calcaneo-valgus—that is to say, till the back of the little toe touches the outer side of the leg. Anything less means imperfect reduction of the deformity, though I have before pointed out that all the classic methods of treatment stop when a range of movement rather less than that of the adult foot has been obtained.

The second crucial point about manipulation is that this full correction (note that it is not an "over-correction") must be obtained at the first manipulation, and that it is gained by a final compression of the whole tarsus as the foot is squeezed against the leg. This primary violent compression of the tarsus has an effect totally different from that of the gradual "coaxing" pulling round of the foot that is at present taught. When the foot is slowly pulled round it gives at its weakest point, the junction of the tarsus and the metatarsus, leaving almost unaffected the centre of the deformity, where the strong bony block below the tibia is left bent and tilted to the curve of the inner concavity of the uterus that has originally moulded it.

I know from experience that of these two principles of manipulation the ambition of gaining full calcaneo-valgus will be accepted by very few people, and the gaining of it at the first manipulation by fewer still. But I am convinced that in them is the essence of the matter.

Finally, it is this same forcing up of the foot into calcaneo-valgus that is the one and only manipulation necessary in the after-treatment. The more intelligent mothers can be taught to do it, but it is extremely difficult to get trained masseuses to carry it out. Without exception they explain that it will "spoil the arch of the foot," and persist in a curious variety of manœuvres which they have been taught, and which seem to me completely useless. After eighteen months or so it usually becomes impossible to push the foot up completely, but a range of movement up to 45 degrees above the horizontal should be kept permanently.

SPLINTING

Once more I beg leave to indulge in a platitude: it is that function is more important in any disability than structure. By correcting the position of the foot and keeping it at rest structure alone is treated. To correct function, the two most important divisions of which are the muscle balance of the foot and the mental impression of how it should be used, it is necessary to allow (and even to stimulate) movement in the corrected position. The classic methods of splinting talipes ignore function. But even in dealing with structure they appear to be inefficient: none of them hold the foot corrected in relation to the body as a whole, though it is on that relation that its proper use depends.

My present model of splint, about the twelfth of its line, is fairly well known. It depends on the mechanical principle that it is possible to control the position of one foot by means of the other. I could easily design one that would be more efficient mechanically, but it would be much more expensive, and would be even less efficiently used. To get the full valgus position that is essential I pack up under the anterior and outer part of the foot with layers of thick adhesive felt. The elastic pressure gained by this is very efficient in moulding the foot; but I have never seen it applied in my way by anyone else. Points in applying it are:

1. Bandage each foot separately. I have been rather depressed by seeing an illustration in a recent book showing a foot being bandaged in with the cross-bar in position (Burns and Ellis, 1937).

2. Fasten the sole-plate first, with the foot packed up in such a manner that the leg-piece projects outward away from the leg. Then when this in its turn is bandaged, it pulls the foot into valgus. I believe it is impossible to overdo this valgus position.

3. If there is a normal foot arrange it in the normal position, pointing outwards from the sagittal plane about 20 degrees. The talipes feet should be arranged to point more outwards, into the "Chaplin position" (here, for the first time, is a true over-correction).

4. Do not be alarmed by a fair amount of reactionary swelling after the first violent manipulation. I have never seen any trouble from this.

5. Never cease the splinting because of pressure sores or skin irritation. Both are rare, neither is important; but if a half-corrected foot is set free it will become far more obstinate than if it had never been touched. (Compare the results of putting on plaster-of-Paris at irregular intervals.) If a baby with simple talipes is put in splints in the first few weeks, full correction and subsidence of reactionary swelling should be attained by the age of 4 or 5 months. Then the sticking-plaster can be left off, and the child supplied with night boots of the same pattern. If the mother carries out instructions and pushes the feet up three times a day to full

calcaneo-valgus there should be no further trouble. I have often found that children treated in this way learn to walk earlier than their normal brothers.

OPERATIONS

The correction of the deformity by moulding with the splint is only possible while the bones are so soft that they will yield before an amount of pressure that the skin can bear without sloughing. On cases which have passed this stage I have for some time been operating according to principles that go flatly against the usually accepted teaching. Sir Robert Jones, for instance, says that as much correction as possible should be gained by wrenching and plaster (that is to say, by stretching the soft parts) before touching the bones; and then that as little as possible ould be removed. Now it seems to me that a foot it has been wrenched, or one in which the soft parts 're been cut or shifted, is in a state of tension that is towards relapse. Stretched fibrous tissue and, even e, scar tissue produced by cutting tendons and liga- s, when once left free contract with force and per- sistency, reproducing the original deformity in a more intractable form. But bone, when once its shape is changed, has no such elastic recoil. In consequence I have been acting on the principle that the soft parts should be left untouched and unstretched, while enough bone is removed to allow the foot to be brought into about the degree of calcaneo-valgus possible to the civilized adult. The situation of the bone removed depends on seeing the deformity as I have described it; it is in a quite different place from the ordinary wedge resection of the tarsus, which has such a deservedly bad name. A most important and usually overlooked part of the deformity is that the external malleolus is too far from the ground, and bone must be removed to let this down to its proper position as well as to allow the foot to be straightened. It might be called a "crescent resection" of the tarsus, the base of the wedge removed being of this shape.

The results I have obtained with this operation have modified my opinion, gained from experience of other methods, that the use of open operations in this condition was to repair the effects of other open operations. I am not as sure of its value as I am of that of the splint I have described, but I am inclined to think the principle sound. If anyone should wish to try it the main points to remember are to go up as high as possible in front of the ankle, and not to be afraid of overdoing the valgus by removing the outer part of the os calcis.

N. Fastuline (*J. Medical (Ukraine)*, 1937, **7**, 1, p. 75) has investigated the bacterial flora of the air at different altitudes in the Caucasian Mountains. He used Mickel's tubes fitted with Janet's syringes. Each test was carried out with the filtrate of 200 litres of air. The mountain air was found to contain saprophytes and no bacteriae of faecal origin. Above 10,000 feet there was a predominance of mycobacteriae over bacteriae. Among the mycobacteriae the author found penicillium and mucor, among the pigmented cocci *Sarcina lutea*, *Micrococcus roseus*, *Micrococcus citreus*, and *Sarcina rosea*, and among the bacilli *Bacterium mycoides*, *Bacterium subtilis*, and *Bacterium mesentericus*.

MODERN METHODS OF TREATMENT OF CLUB-FOOT*

BY

E. P. BROCKMAN, F.R.C.S.

Orthopaedic Surgeon, Westminster Hospital

In the past the treatment of congenital club-foot has undergone many changes, and in the future it will probably experience others. No generation is ever satisfied with what its forbears have done; this is a right and proper attitude to adopt, otherwise progress or improvement would cease.

Whatever our views as to the pathology or treatment of this deformity, and they are many and varied, it still remains a condition which, however satisfied the surgeon may be, is capable sooner or later of making him appreciate his own limitations; for the orthopaedic surgeon who has treated this deformity over any number of years must time and again have had patients to whose parents he has said, "This child's feet will not relapse," and yet perhaps one, two, or even several years afterwards the patient has been brought to him with the story that the feet began slowly to turn inwards again. You have already listened to an account of the deformity of congenital club-foot in all its aspects. I therefore propose to confine my remarks almost entirely to its treatment.

Some years ago I spent a considerable time upon an investigation of congenital club-foot, and I have not changed my views as to its pathology and aetiology, except that in regard to the former I have realized that the changes in shape of the individual bones of the foot are more marked than I thought at that time.

You probably all know my hypothesis that congenital club-foot is due to a congenital dislocation of the head of the astragalus, that this dislocation is due to an atresia of the socket into which the head of the astragalus normally fits, and that therefore the deformity results from an intrinsic and not an extrinsic cause. I believe this hypothesis is as good as or better than any other, and that it explains more satisfactorily the difficulty we experience in our treatment of the deformity. If the deformity were due entirely to the effects of outside pressure, as is still commonly believed, it should be a simple matter, by exerting a similar pressure in the reverse direction, to correct the deformity and hold it corrected until such time as it was possible for the child to maintain the corrected position by its own muscular power. This I think we must all admit is not in practice what does happen.

From the methods of treatment usually advocated there cannot be any question that in a great many cases the condition is not cured by simple means. We all get cases in which the feet respond to treatment, but we have plenty in which the results are unsatisfactory.

Treatment in the Infant

After a long experience of the method of treatment upon which I was brought up—namely, repeated forcible manipulation of the deformed foot and fixation of the foot in the corrected position with plaster strapping—I have come to the conclusion that it is a poor method in every way when compared with the one advocated by Mr. Denis Browne. It needs frequent repetition several

* Read in opening a discussion in the Section of Orthopaedics, including Treatment of Fractures, at the Annual Meeting of the British Medical Association, Belfast, 1937.

times a week; it hurts and frightens the child; it upsets the relations, who regard it as rather brutal, as in fact it is; it frequently has to be interrupted because the skin of the foot becomes sore; and, last and most important, the use of strapping to maintain position after manipulation is useless once the child becomes of any size, as the patient is able by the contraction of the muscles to pull the foot round in spite of the strapping.

For some time I have used the splint invented by Mr. Denis Browne, and I find it avoids nearly all these troubles. Perhaps, to begin with, several manipulations are necessary to enable the splint to be applied, but thereafter it can be reapplied without these forcible manipulations, which must and do inflict severe trauma to the tissues of the foot, causing swelling and a synovitis of the joints with ultimate stiffness of the foot as a whole. With this splint the child very soon realizes that it is not being hurt, as also does the mother, and instead of a screaming child one has an infant which gives no trouble. It is a splint by which it is easy to apply the correction gradually, and I think it illustrates one of the great principles of orthopaedic surgery which in the present day of operation and impatience to get results we are apt to lose sight of. I know it is unwise to generalize, but I have myself learnt that, speaking generally, haste in the correction of deformities does not pay, either from the view of the patient or from that of the surgeon. This I believe to be the very great merit of Mr. Browne's method of treatment in the infant. The older orthopaedic surgeons before the war were slow in their methods of treating congenital club-foot, but the testimony of some of the sisters who worked with them was that they, as a whole, got better results than do the present generation.

Mr. Browne on former occasions has deprecated the method of repeated forcible manipulations under an anaesthetic and of fixation in plaster of feet which have not responded to early treatment. With this I am in entire agreement. I have spent many hours manipulating such feet, with very indifferent results. His views are that the foot becomes stiffer each time it is manipulated, and that the muscles of the leg, as the results of long periods of fixation, become more and more wasted. This is certainly true, and once the muscles have become really wasted and hardened they never, in my experience, become supple again or properly developed. If, instead, the foot is manipulated once under an anaesthetic to get it plantigrade and this splint is then applied it is extraordinary how, at the end of a week or ten days, it appears to have softened out: also the splint can be reapplied without any trouble, a little more correction being obtained by gradually rotating the foot outwards.

Not only do the adduction and the inversion, which are really one deformity, improve, but in addition that most troublesome feature of congenital club-foot, a small drawn-up heel, appears in many instances to descend without any trouble. The child probably, by pushing against the splint, gradually stretches the tendo Achillis.

I have not, I must confess, employed this method long enough to be able to express an opinion as to whether feet thus treated have less tendency to relapse, but it most certainly is the simplest method to employ in the infant and does not have the disadvantages of the others. I would certainly commend it to any who have not so far employed it.

Many surgeons still hold that when the adduction and inversion portion of the deformity in the infant has been corrected the equinus, if it persists, must be dealt with by a division or elongation of the tendo Achillis. My own view in this respect is that division or elongation of this tendon, however done, does result in considerable muscular wasting, and my experience is that the position of the foot very often cannot be corrected afterwards and that its condition is worse than it was previously.

We have all held that the criterion of cure in a congenital club-foot is "a foot with no adduction or inversion; the presence of a hollow upon the outer side of the foot in the position previously occupied by a bony mass, the head of the astragalus; the ability of the child voluntarily to evert and also dorsiflex the foot well above the right angle." As I have said on a previous occasion, even if this criterion is fully obeyed it cannot be claimed that the deformity will not relapse. I still find this to be true. When a deformity does relapse I believe that the correction which had been obtained before must have been a spurious one, and that the deformity had in fact been hidden by a false correction of the fore part of the foot.

We then come to consider the treatment of those deformities which have not been cured by conservative means and require some form of open or bone operation.

Open Operation

The basis of the open operation which I devised depended upon my hypothesis that the socket for the head of the astragalus was too small to allow the head to enter and articulate with it properly; that in order to enlarge the socket, which was contracted up, it was necessary first to elongate the muscles controlling the alteration in size and then to divide the calcaneo-scaphoid capsule, which was also contracted, thus permitting the bony portions of the socket to take up their normal relation to the head of the astragalus and the other bones of the foot. In theory this seemed a rational operation and one which it would appear to be quite easy to carry out.

Actually in practice it is sometimes impossible to achieve what one has set out to do. I have realized more and more that by the time I have come to consider open operation the shape of the tarsal bones, especially the head of the astragalus, has altered more than I originally appreciated. Sometimes even if the position of the scaphoid and os calcis with relation to the head of the astragalus can be altered satisfactorily it will not remain thus, because it is impossible for bones which do not fit each other to articulate in anything like a normal manner.

I am not in a position to give you the late results regarding the patients upon whom I operated originally and upon whom I probably lavished more care and attention, but I can give you the results of the operations I have done since 1929 in the ordinary routine of hospital work. Some of these patients have quite good feet from a functional point of view, but, as is only reasonable, not so good as the ones treated by conservative methods only. There is a very real danger of the foot becoming valgus and boat-shaped if the open correction is easy. Once such a foot has been produced I know of no method short of an arthrodesis that will remedy it. It is impossible when a valgus foot has been brought about by an open operation to correct the condition subsequently by any forcible manipulation. Some such feet I have had to assist afterwards by means of valgus supports. In two cases I have been compelled to fix the foot in a better position by means of an arthrodesis of

the midtarsal and subastragaloid joints because the foot was in such a bad position.

A great many patients upon whom this open operation has been carried out have returned to me months or even three or four years afterwards with a relapsed and rigid foot. In some few instances one or more manipulations, followed by suitable boots and exercises, seem to have restored the position, but in many resort to a bone operation has been necessary to deal with the deformity.

Another thing noticed in the late results of this operation is that the foot very often is much thicker in the midtarsus, and also there is a tendency for a persistent equinus to remain. This does not seem to cause any disability, but it gives the foot a rather ugly appearance. On the whole I think some feet can be improved by this method, but it appears to be very difficult to be in any way certain which cases will be permanently successful.

What has been found at operation upon those feet that have relapsed subsequent to an open correction? The midtarsal and subastragaloid joints were full of fibrous tissue binding the opposing surfaces of the bones together. This fibrous tissue was so firm that it had to be dissected away before the articular surfaces could be identified. It was quite obvious that subsequent to an open correction there must have been little if any movement in the joints. And clinical examination of feet upon which this operation has been performed has demonstrated that there is scarcely any movement. They are always rather stiff feet.

Repeatedly I have found that the scaphoid and os calcis, which at the time of the open operation had been restored to a satisfactory position so far as one could see, had returned to their original relation with the astragalus—the scaphoid on the inner side of the head and the os calcis tilted beneath it.

Bone Operations

I still believe that when all other methods of treatment have failed an arthrodesis of the subastragaloid and midtarsal joints, removing at the same time sufficient bone at these joints to produce a correction, is the best and most lasting method of treatment. It is an operation which gives a very satisfactory foot in a talipes equino-varus the result of an infantile paralysis, and it is the rational operation to perform in the deformity we are considering. I would even go so far as to say that if there is any doubt about doing an open correction an arthrodesis is probably the better line of treatment. Astragalectomy and other piecemeal bone operations should still be condemned.

To conclude, with regard to the vexed question as to whether there is or is not any inward rotation of the tibia I still hold that the real fault is a failure to correct the deformity of the foot, and that osteotomy is simply the production of one deformity to hide the existence of another.

Issued as a special supplement to *The Countrywoman* of August, 1937, is a report prepared by the Associated Country Women of the World on midwifery services in rural areas throughout the world (30, Baker Street, London, W.1, price 3d.). In a brief discussion of the report Dr. Esther Carling compares the state of affairs in America, where in New York State, for example, only 2 per cent. of deliveries take place outside hospitals, with that in France and other European countries, where the avowed policy is to make it safe and possible to have all babies born in their own homes. A mass of information is compressed into relatively short space in this publication.

INSTINCT AND HYSTERIA*

BY

PROFESSOR ERNST KRETSCHMER

Director, Psychiatric and Neurological Clinic, Marburg University

The study of mental diseases is not only interesting in itself, as a means of helping the patient medically, but is also of scientific importance in that it opens up the most important avenue to a knowledge of the biology of the healthy man and to an understanding of the nexus between psychological and physical phenomena. Typical psychic mechanisms appear in psychopathology in exaggerated relief and can help in the solution of general biological problems. In the same way the thorough study of general biological laws assists in the more profound understanding of psychic symptoms. Thus, formerly we studied how far hypnoid conditions in hysteria might be compared to the phenomena of the so-called "animal hypnosis." In particular we have compared the motor patterns of hysterical tremors, attacks, stupors, and paralyses to the mechanisms of instinct, the flight and defence reactions which in the animal we call violent motor reactions and the sham-death reflex.

Relation of Hysteria to Animal Instincts

The view that certain hysterical reaction types are in close relationship to animal instincts in general is especially confirmed by the large mass of those types of reaction which centre round the impulsive life. Hysteria originates especially from two main sources: (*a*) the instinct of self-preservation—in the form of fear and anxiety in relation to dangerous situations—and (*b*) from all the emotions and conflicts associated with the sexual life. Wishes, struggles, and disappointments of an erotic nature form the main group of experiences which produce hysteria in ordinary civil life, especially in women. The shock neuroses provide another very large group of hysterical reactions—not, however, in the sense that acute fright syndromes, for example, are merely identical with the hysterical neuroses which develop from the frightening experience or from chronic anxiety, but in the sense that both have a close relation to, and dissolve into, each other.

No agreement as yet has been fully reached on the question of the relation between hysteria and the fright neuroses. Even though the acute fright reactions have often been simply labelled as hysteria in consequence of their unmistakable resemblance thereto, nevertheless a sharp boundary line was drawn between them so long as the fright neuroses were only considered as acute, automatic, evanescent, and spontaneously resolved affective reactions; whereas hysteria, on the contrary, was only spoken of when such acute reactions became secondarily fixed through the purposeful intervention of a "will to sickness," a "gain from sickness." That these difficulties are not due to deficient observation on either one side or the other, but arise from the nature of the problem itself, will soon be apparent.

Reactions to Fright and Danger

What reactions do we observe as a direct result of situations which produce fright and danger? The subjects are shaken, tremulous, irritable, and confused; they

* One of three lectures given at the Tavistock Clinic in April.

mostly complain of physical symptoms—headache, insomnia, misery, palpitation, fatigability, dyspnoea on walking, and excessive reactions to damp and heat. They often exhibit great temperature oscillations and abnormal eruptions, and have exciting and very vivid dreams. An absolutely reliable and ordinary type of man is entirely altered—he is now tremulous, irascible, excited, incapable of concentration, exhibits dyspnoea on walking, palpitation, insomnia and headache, and pyrexia after such exertion as mountain climbing. The patients admit often feeling well, then again they will complain of headache, which is possibly present seeing that at such times they have bloodshot somewhat bulging eyes and a secretion of tears. During such phases they have pyrexia and a pulse rate of 100 or 120.

Similarly Bonhöffer describes the vasomotor symptom-complex as the most characteristic effect of fright. As belonging to the acute psychogenic effects of fright Gaupp mentions severe tremors, tachycardia, hyperaesthesia, fearsome dreams, polyuria, vasomotor secretory symptoms, and delirious clouding of consciousness. Among the survivors of the Messina earthquake in 1908 Stierlin chiefly found insomnia, increased reflexes, and rapid and fluctuating pulse.

We might say, therefore, that disturbance of the vegetative nervous system, with vasomotor manifestations prominent, is the most common feature of fright syndrome. And the resultant general instability of physical and psychic functions offers a favourable soil for the development of various types of hysteria, although only a minority of subjects will become hysterical; in the majority spontaneous recovery will occur after a certain time. In these syndromes a psychic aim is not as yet demonstrable; they are to be considered as purely reflex.

When in those special fright syndromes psychomotor or purely psychic functions are involved, the matter of interpretation is more difficult; above all, in those pictures which resemble the "sham-death reflex" and the "violent motor reaction"—the fright stupor, the twilight states, senseless running away, tremors, and convulsive attacks. According to their external symptomatology these pictures do not differ fundamentally from the usual hysterical reactions which occur in the absence of acute shock as a result of emotional disturbance. Nevertheless we may say that the acute fright syndromes are distinguished to a certain extent from the ordinary hysterical reactions by a strong predominance of vegetative vasomotor signs, by their tendency to more primitive physical effects, convulsions and twilight states, and also to a certain degree by the pure forms of fright stupor.

Is it possible always to differentiate between the fright reactions and hysteria according to their inner psychological structure? Observations on shock psychoses of recent occurrence and of short duration in vigorous men have resulted in the following description: "It was possible on seven occasions to observe directly the awakening from the exceptional condition. The contrast between the twilight state in which the person exhibited theatrical behaviour, which in individual cases went so far as puerilism and nonsense talk, and the awakened state was quite astounding. As a rule it was difficult to realize that this now smart, self-contained, inconspicuous man was the buffoon of the twilight state. The awakening occurred suddenly."

From such observations it follows that even the acute psychic fright syndromes do not produce manifestations so automatic and physiologically limited as to "knock out" the psyche, but that they frequently contain elements which point to an active psychic participation which—therein lies the important point—exhibits a directly purposeful quality. Not only do the precipitating fright-experiences often undergo repression or transformation ("The man has fallen over," says a patient in a fright-twilight-state, instead of "He has been killed"), but the fright-twilight-state, also, even in vigorous and brave persons, may in a remarkable manner assume forms we are otherwise accustomed to see in criminals and to regard as signs of crude hysterical deceptive tendencies, bordering on simulation—the Ganser syndrome with its falsely directed theatrical behaviour.

Examples of Fright Reactions

Stierlin also reports numerous examples of similar fright reactions from the earthquake catastrophes of Messina and Valparaiso. A certain incomprehensible composure or even a contrasting cheerfulness with repression of the terrifying experience was the most frequent psychological sequel of the catastrophe. In many cases, however, this tendency to repression proceeded to take the form of puerilism or of a ludicrous pseudo-dementia. "Thus, on the morning of the earthquake at 7 o'clock, a man of prominent position, who together with his family had escaped death, was seen in a nightgown sprinkling the flowers in his garden with a watering-can. Another, a merchant who had lost his house and family on the day of the calamity, was seen on the quay in his nightgown and slippers with a large herring in his hand, laughing to himself." "Another person who had lost his family in the earthquake, and had escaped with nothing more serious than shock, did not appear as though the disaster had made the slightest impression upon him. It seemed to mean nothing to him, although he saw his house in ruins and heard the catastrophe being discussed. He appeared to be delighted, and rode round in his motor car. When anyone spoke to him he was much confused, and kept on laughing. Yet in ordinary circumstances he was a good, sound family man." "After being thrown out of the window by the atmospheric pressure, a 17-year-old youth, as though by a miracle, landed uninjured on a meadow. Without showing the slightest concern for his family, he wanted to assist with rescue work, during which he played the clown. His severe confusional state lasted for more than a week. During the whole of that period he showed no kind of concern for what had happened, and never inquired about his family nor about anyone's safety. He seemed to know nothing about the whole event. One could see him aimlessly wandering about the streets in his shirt-sleeves." "Night after night a 65-year-old bank official ceaselessly called out 'Papa, mamma; Papa, mamma.' He imagined that his physician was a marshal, and addressed his own son as father."

It is scarcely possible to avoid the conclusion that the acute fright reactions often include from the start a tendency to flight from unbearable circumstances into a peculiar state, involving both repression and theatrical behaviour—in other words, the very psychic reactions which are nowadays usually regarded as forming the specific nucleus of hysteria. We shall more readily recognize the close relationship between fright neuroses and hysteria when we remember that both have a common biological origin—namely, the general animal instincts of defence.

How Hysteria and Fright Reactions Differ

Yet we must differentiate between hysteria and the fright reactions. Certainly acute terror (equally chronic

anxiety arising out of acute fear) is one of the most favourable starting-points for hysterical formations. But the fright neurosis remains essentially an *acute* syndrome, whose features are stamped by the severe affect of the moment, and which lasts only throughout the period of affective strain. The purposive factor has not as yet achieved independent expression, but is vaguely inherent in the anxiety-affect in much the same way as the tendency of a drowning person to clutch at a straw may be regarded as belonging to his anxiety-affect. In the case of the true fright neuroses both repression and theatrical behaviour disappear automatically *pari passu* with the after-effects of the acute shock. The patient comes to himself as the clear, energetic person he was previously; and again takes up life at the point where he left it. Most acute fright reactions end in that way. A new factor enters into those fright and anxiety reactions which develop into chronic hysteria. With the gradual return of reflection and composure the patient enters on a transitional phase in which the residua of the acute mechanisms become influenceable by the will, inasmuch as he is able to suppress them entirely or to allow them to develop still further. This is confirmed by my own clinical experience as well as experimentally. If during the return to normal the egotistical wish for a permanent removal from the danger-zone or for material gain secures the upper hand, it may interfere with the subsidence of the affective automatisms and give rise to a fixation. He is still in a position to fall back on a relapse into an acute anxiety, or twilight, state; the slight original tremor of predominantly autonomic origin can be reinforced so as to produce coarse tremors and shaking attacks.

Therefore, if we wish correctly to understand the relationship between hysteria and fright neurosis we must distinguish between two aims: (*a*) the primary aim, the primitive flight or defence tendency inherent in every strong painful affect and which forms the basis of the repressions and theatrical behaviour met with in the acute fright reactions; and (*b*) a secondary aim, which only makes itself felt during the subsidence of the acute affective shock and the return to normal, and which now produces a chronic hysteria out of the acute fright syndrome. It is at this stage that we can speak of hysteria proper. The acute affect, which includes the aim, dominates in the fright neurosis. In hysteria, originating from acute affect or from a chronic fear for one's life, the more lasting aim, which influences and utilizes the residua of affective mechanisms, governs the picture more and more. The former, the fright reaction, is essentially instinctive, created by a momentary, overwhelming situation. The latter, secondary hysteria, is more on the boundary between the instinctive and the rational, and, more than the former, is the product of the entire personality. That is why we are unable to separate the fright neuroses from hysteria, but also cannot identify them with each other.

Physiological Reflex Mechanisms in Fright

Is the acute fright reaction a purely physiological reflex in which the psyche as such does not participate, or does it depend, hysteria-like, on auto-suggestion? According to previous observations, we will answer this question as follows: In the acute pictures of fright physiological reflex mechanisms are just as surely demonstrable as hysteria-like elaborations of experience. The autonomic-vasomotor symptom complex may serve as a characteristic example of the first type, and, psychically speaking, directly includes the disturbance of sleep as well as the affective instability anxiety and depression. Also certain twilight states with predominantly organic features, observed by Bonhöffer, and many epileptic-like convulsive attacks fall into this group. On the other hand, the twilight state of the Ganser type, with its fright-manifestations, best exemplifies the direct psychic elaboration of fright reaction with hysteria-like mechanisms. The direct acute fright syndromes represent varying combinations of these two main factors; frequently they appear inextricably mixed in the same symptom-picture.

It is of significance in considering the relationship between the instincts and the hysterical reactions to note that the "major hysterias" with their richly developed massive symptomatology—for example, reflex mechanisms, violent motor reactions, stupors, paralyses, and twilight states—are commonly associated with situations which conflict strongly with the impulsive life—that is, with the erotic instincts and with the instinct of self-preservation. In the war one saw these massive hysterias develop not only as the result of acute, dramatic fright situations, but still more frequently they developed out of gradually progressive anxiety for one's safety—for example, behind the lines or in a military hospital where there was a dread of further exposure to danger. The reverse is true of such purposive neuroses whose secondary gain is not so directly anchored in the impulsive life—for example, the compensation neuroses of civil life. These are characterized by their diffuse symptomatology, their vagueness, and by the frequent absence of reflex, hypobulic, and hyponoic mechanisms. Only where the impulsive life is closely impinged upon do we come across the primitive instinctive reactions—for example, violent motor reactions and sham-death reflexes.

Hysteria and the Sexual Impulse

Let us now consider the relationship between hysteria and the sexual impulse. One aspect of these relations was emphasized in general medicine, and still more in Freud's psycho-analysis; they were even regarded as the governing principle in the theory of hysteria. As a reaction against his over-emphasis they have at times been understated. In short, it must be admitted that there is an important nexus between hysteria and that instinct, but this relation is not invariable. The sexual impulse only comprises one-half of these relations; the other half, which is just as important, is formed by the hysterical fright and anxiety reactions.

In the development of an individual case of hysteria combinations and anastomoses frequently occur between the sexual impulse and the fright-anxiety group. In neurosis a repressed sexual impulse often manifests itself as anxiety. On the other hand, especially in children, genuine anxiety can accompany sexual excitement. Thus we find hysterical reactions which have long been dormant in the form of an erotic psychic conflict are suddenly released by a fright-producing experience. A woman, who is getting old, enters into a severe state of inner tension and jealousy over the engagement of her younger sister; one day she is terrified in the street by a team of frightened horses, and suddenly exhibits hysterical abasia; she had never before reacted hysterically to fright. And, therefore, one impulse-stimulus can blend with another, so that combined they can produce an hysterical reaction.

Women and girls exhibit sexual hysteria more frequently than men. It would lead us too far astray if we were to give in detail all the erotic conflicts which might give rise to hysteria. Amongst the most frequent we might

mention: an unsuccessful love affair, jealousy arising out of the marriage of a sister, an undesired marriage, fear of pregnancy, difficulties in sexual intercourse, an unhappy marriage. At one moment the physical, at another the psychic side of the sexual impulse is the more hysterogenic.

Constitutional Foundations of Hysteria

For our present thesis the constitutional foundations are more important than individual experiences. Apart from war and compensation hysterias, our observations (which concur with Kräpelin's) show that the majority of hysterias occur round about the age of puberty, and much more frequently in the female sex. As is well known, the age of puberty is the most susceptible period for the release of constitutionally determined anomalies. As a matter of fact, we find an astounding number of constitutional anomalies among our hysterical material: infantilism, which generally manifests with special strength in the field of sex. Our clinical material of the last few years is especially rich in physical asthenia, genital malformations, dysmenorrhoea; and in the psychic field, general childishness, weakness of the sexual impulse, aversion to men, an over-strong psychic fixation on the mother, a generally disturbed pubertal development with retardation, or uneven establishment of the separate manifestations of puberty. In contradistinction to the compulsion neurosis, the signs of sexual infantilism are very frequently found in the hysterias; but the cruder perversions are relatively seldom present. Homosexuality most frequently manifests as an exaggerated and erotically coloured enthusiasm for girl friends, which may again be interpreted as an increased or a prolonged phase of an essentially normal early pubertal phenomenon; it can therefore be considered as only a partial manifestation of the infantilistic disturbances of puberty.

As an example of such a disturbance of pubertal development in hysteria we may mention the following case. A 22-year-old girl, who exhibited bad temper, hysterical- twitchings, and an impulse towards self-mutilation, menstruated for the first time in her seventeenth year. Even to this day she has a physical aversion to men, but experiences strong sexual excitement, which, in the manner of young pubescents, she satisfies by fantasy and masturbation. Even now her letters show a mixture of childish naïveté and pathos, a combination of the droll and tragic, characteristic of the "flapper." She said: "If I do not get well father must order my coffin at once, then it will make no difference even if I am damned. Someone may yet come for me. I am forgotten by God and the world. When someone does come, bring mademoiselle's apples to me." She had retained a childish kind of bigotry, and pestered the sensible old local parson with her incessant confessions of all her sins of thought and acts of masturbation. The clergyman well realized that she at one and the same time strove against and gratified her particular impulses in the confessional. Because the clergyman, during confession, was not strict enough with her, she had recourse to a Catholic priest, an alleged exorcist. She soon began to exhibit the usual mixture of adoration and erotism, and, influenced by his suggestions, she rapidly developed into a full-blown hysteric.

Without much difficulty we can perceive how this entire hysterical development of personality, up to the final appearance of twitchings, originated as a result of pubertal arrest, and remains indefinitely fixed in an early pubertal phase. The sexual impulse has retained its earlier structure, and, although lively and urgent, has failed to seek the normal sexual goal. The opposite sex is prudishly rejected. The impulse works itself out, on the one hand, in fantasy and dreams, and, on the other, in masturbation. Her bigotry, too, is nothing more than a tortuous channel by which the impulse finds concrete expression. The constant confessions involve an urgent and continuous preoccupation with sexual matters. After the faulty canalization of the non-adult impulse, it assumes more extravagant religious and semi-erotic forms, and finally, when the affective tension reaches a certain height, culminates in an hysterical motor discharge.

The same thing may happen to the sexually immature woman on marriage. Here also we find, as in early puberty, confused and vaguely compulsive feelings—a combination of disgust and negation with ungratified idealistic yearnings—which oscillate and do not permit of a normal love life, and finally discharge indirectly through the old hysterical instinctive channels. If vital anxiety is added to fright hysteria, then the symptom picture of the more sexually derived hysterias exhibits anger and disappointment together with erotic ecstasy, especially in the form of hysterical attacks and twilight states. There may also be irradiation into the sensory field, involving genital, quasi-genital, or symbolically displaced dysaesthesias.

Such immature women, with the sexual development of a 15-year-old girl, are suddenly faced with the realities of adulthood. That is why the approach of a concrete suitor, who was at first enthusiastically longed for in an idealistic way, or the prospect of marriage, is followed by instinctive defence-reactions, such as convulsions and sham death. Among prostitutes both syndromes—sexual infantilism and a tendency to hysterical reactions—are met with with striking frequency.

Physical infantilism, more often a deficient capacity for love, and exaggerated prudishness and shyness in themselves frequently hinder the attainment of concrete, happy love. Such girls are apt to develop into warped "old maids." On account of their lack of amiability they readily become Cinderellas, and act the part semi-genuinely with their poor affective equipment, martyr-like. "I am a neglected child, no one brings me presents, I never receive justice." She quietly puts up with everything, does not aspire to earthly goods, just requires a modest living, peace, and repose. She finally develops into a pseudo-ascetic bigot, or even exhibits a bitter, rebellious attitude of resentment, involving a permanent warping of the character. Her life is typified by constant friction with brothers, sisters, and parents, expresses itself in little malicious remarks and acts of revenge of an offensive, hysterical nature, lying in bed for weeks, or alarming attacks. Or she may exhibit a sudden dramatic collapse with symptoms of major hysteria, which may occur at a moment such as the engagement of a younger sister. Then once more the perverted impulse shows itself violently as sexual envy, and is discharged in instinctive reactions.

Regression in the Hysteric

Just as the impulsive life of the hysteric is often incompletely developed in a progressive sense, so also it often undergoes regression. Impulsive attitudes proper to childhood continue into adult life, as may often be shown in the relation to the parents. In hysterical individuals, as with many schizophrenics and schizoids, it sometimes happens that a proper resolution of the emotional attachment to the parents and the easy neutral independence of the adult are not attained. With excessive tenderness he remains clinging to his mother. The authority of the father retains its almost god-like quality, so that he

rebels against it violently and yet cannot break away. A 19-year-old youth develops a feeling of paralysis in his arm out of fear of his strict father, who is always urging him to work. In young women one observes hysterias which are wholly directed against the father and the home environment, and attacks which represent stormy impulsive discharges of anxiety and anger against them.

These forms of hysteria constitute a link with the real hysterias of childhood, which partly arise in connexion with the relation to parents or parent-substitutes. In children the relation to the parents is comparable in strength to sexual relations between adults, and is also instinctively derived. Also the close relation of hysterical reactions to fright and anxiety holds good with children as with adults. But there is an important difference—namely, that in children the hysterical forms of expression are generally more closely related to the normal ways of affective discharge than in the case of adults, and, therefore, strong childish reactions to severe painful stimuli merge gradually into what is essentially hysterical. Consequently, in children we more often find hysterias of an episodic, meaningless character which are not rooted in strong impulsive tendencies but arise from transitory momentary affects, imitation, and so on.

Many symptoms of what is called the "hysterical character" are nothing more than the fixed residua of an early pubertal psyche or unfavourable characterological modifications of the same under the altered demands of later life—namely, the characteristic antithesis between coldness and excess of erotic feelings—that is, an over-lively and over-idealistic psychosexuality with prudish rejection of the physical aspects of sex, enthusiasm for impressive persons, a preference for what is loud and lively, a theatrical pathos, a taste for brilliant roles, heroic fantasies, the playing with the idea of suicide, enthusiastic self-sacrifice, combined with a naïve, sulky, childish egotism. An immature psyche of this sort has a greater inclination towards impulsive discharges of affect, and especially towards hypobulic mechanisms. The hypobulic phenomena appear partly as circumscribed hysterical outbreaks (especially in the hysterical attack) and partly as permanent stigmata of the so-called "hysterical character" which, on account of its strongly hypobulic nature, we call capricious, in view of the distinctive contrast between stubbornness and exaggerated suggestibility shown therein.

The Effervescent Type

The effervescent type of psyche associated with early pubescence is very impressive and has been much described; but in our experience it is by no means the form most frequently given to hysterical reactions. Hysteria is more common in banal and stunted types, often exhibiting infantile stigmata, both physical and psychic, intellectually weak, annoyingly apathetic, emotionally defective, anxiously shy, fearful and excitable. They comprise the whole army of markedly psychically defective persons, the mental defectives, criminals, and prostitutes, who, not because of a specific mental structure, but simply on account of their deficiency of higher psychic mechanisms, are inclined towards primitive impulsive psychic discharges, which frequently include hysterical reactions. Further, hysterics seldom belong to what is known as the "cold-blooded type," but when they do belong to that group the hysterical reactions which they show are very rich and fully developed. This type is cruel, capricious, dishonest, thievish, completely amoral, unfeelingly egotistical, malicious, and intriguing. Many of these traits have been included in the description of the so-called "hysterical character." It is in point of fact a less common definitely degenerative type bordering on moral imbecility and the schizophrenic group. Furthermore, it is well known that the type of "congenital swindler" is very much inclined to hysterical reactions.

The Age Factor

In general one may say that puberty provides the main occasion for the exhibition of hysterical reactions and developmental retardation. The presence or persistence of early pubertal psychic stigmata most easily gives rise (in addition to the severer forms of psychic defect) to the "hysterical character"—that is, to a consistent tendency for the release of hysterical reactions. Hysteria is above all a reaction-form "of naïve, undeveloped psychic life" Kräpelin); it has its roots in the impulsive life. The nearer a person approaches an archaic psychic level or the more he regresses, the more does his hysteria take on the character of a severe pathological abnormality based on degeneration; and even then only when an extremely severe experience can be excluded. In youth hysterical reactions may betray a markedly degenerate constitution, but not necessarily so.

Why do hysterical cases become increasingly rarer with advancing age? Undoubtedly because in the course of time the slighter anomalies of pubertal development do, on the whole, become adjusted, and because, in general, many varieties of hysteria have no serious abnormal constitutional background, but appear episodically in children and the young as adventitious instinctive reactions to adverse experiences and environment. Kräpelin established this fact when he said that a large proportion of his female hysterics were country girls who, as young servants, had become transplanted into a large city and were not quite equal to the change of environment. Here again one is reminded of infusoria in a pond, which, on approaching a zone unfavourable to life, immediately exhibit "violent motor reactions."

With very severe experiences, such as war or earthquakes, not only the young, but even occasionally normal adults may show panic, hysterical reactions, or shock-neurosis. Thus we may conclude with Hoche that "everyone is potentially an hysteric"; for we are all carriers of archaic patterns which are usually more or less efficiently covered by more recently acquired cultural and characterological strata.

Thus hysterical reactions are to be regarded on the one hand as being congenitally determined, and as stereotyped expressions of life, which appear under common and everyday conditions, but especially at vital crises. Hysteria-like reactions are, on the other hand, also stereotyped responses of human and animal organisms to intolerable experiences, and are thus closely related to healthy psychic life.

The Industrial Welfare Society has arranged a course of three lectures to explain the far-reaching changes in factory law brought about by the new Factories Act. The lectures are being given by Mr. H. Samuels, barrister-at-law, at the headquarters of the society, 14, Hobart Place, Westminster, S.W.1, from 6.30 to 7.45 p.m. on Thursdays, September 16, 23, and 30. The fee for the course is £1 1s. (15s. in the case of member firms). The course will be repeated in Birmingham on Wednesdays, October 6, 13, and 20, at 6.15 p.m., at the English Theatre at the University.

AIDS IN THE DIAGNOSIS AND TREATMENT OF ECTOPIC GESTATION

BY

W. C. W. NIXON, M.D., F.R.C.S., M.C.O.G.
Professor of Obstetrics and Gynaecology, University of Hong Kong, and Government Consultant

The diagnosis of ectopic gestation in all its varieties is notoriously difficult, and for the attainment of some certainty in this it is necessary to evaluate carefully the history, symptoms, and signs. Proper treatment depends on a correct diagnosis, and doubtless there are cases in which the condition is unsuspected and entirely missed. By an error in diagnosis one may unnecessarily be exposing a patient's life to grave risks. It is thus incumbent on one to marshal all facts that may assist in the elucidation of the disease from which the patient may be suffering.

Acute tubal rupture with severe internal haemorrhage and its dramatic sequence of events is known to all. This is the picture of ectopic gestation which the recently qualified doctor has in mind. In actual fact it is surprising how rarely one sees the acute compared with the subacute or chronic (haematocele) type. A proper orientation and perspective of this disease and its common manifestations is required. Shaw (1936) states that "the diagnosis of ectopic gestation, in which localized haematomata are formed, often presents an extremely difficult clinical problem, and a careful interrogation of the patient as to the severity of the pain is always necessary." Cope (1935) refers to Grandin's observation that "the man who suspects every woman of having the condition is the man who is least liable to err in diagnosis." It may be considered that this is an overstatement, but with increasing gynaecological experience one appreciates that it is not so. A mass in the pelvis may be due to many causes, but in considering ectopic gestation the usual mistake made is between this and tubo-ovarian inflammation, an ovarian tumour or an early uterine pregnancy with a small tubo-ovarian swelling (inflammatory or neoplastic). With acute tubal rupture the condition has to be diagnosed from other abdominal catastrophes such as perforation of a hollow viscus. Most gynaecological surgeons will admit that at some time during their careers they have mistaken an ectopic gestation for a threatened abortion.

Pelvic Haematocele

As aids in the diagnosis of pelvic haematocele I wish to stress the importance of certain points in the history and the presence of *pulsation* in one or other vaginal fornix. Cases will be cited as illustrations.

With regard to the history, in something like 30 per cent. (Whitehouse, 1935) of cases there is no definite interruption of the periods, as irregular bleeding makes its appearance at or before the time when the first period following conception becomes due. I have noted that bleeding of an intermittent character may start before the period is expected or it may be coincidental with menstruation. On the other hand this may be delayed for a few days, and then blood loss be continuous for some weeks. One can almost invariably elicit a history of pain in the lower abdomen, present perhaps for one day only but in most cases recurring at intervals and being of a colicky nature. Eventually it may settle down to become a continuous dull or dragging ache. The combination of repeated attacks of pain and bleeding is most significant. Where the haematocele is large the main complaint may be bladder distress.

Pulsation in a Fornix

Writers in the last century were fully aware of this sign. Allbutt (1896) states: "Some authors have enumerated among the symptoms, during the progress of haematocele, an undue pulsation of the arteries in the vagina and cervix uteri." Whitehouse (1935) says that "pulsating vessels are often to be felt." In distinguishing tubal pregnancy from a tubo-ovarian swelling associated with an early uterine pregnancy he says that "the presence of definitely pulsating vessels on the affected side only favours a diagnosis of tubal pregnancy." Contrarily, Munro Kerr (1933) does not attach great importance to this, for he has observed that in inflammatory conditions of the appendages it is also well marked.

I have found pulsation in one or other fornix to be of considerable help in arriving at a correct diagnosis, and I cannot easily reconcile Kerr's statement with what I have experienced. In this part of China (Hong Kong) pelvic infection, due either to gonorrhoea or to septic abortion, is rife, and pelvic abscess is commonly seen. As yet a haematocele has been the finding at operation in every case in which there was pulsation. In some of them the husband has been known to be infected with gonorrhoea.

It is easy to miss the presence of pulsation in a fornix. The tip of the index finger should rest gently in the region of the attachment of the vagina to the cervix. It is there that pulsation is best felt. Only light pressure should be applied, for if it is too firm then the pulsation will be obliterated. For the elicitation of this sign in the right fornix it is preferable to use the left index finger.

Illustrative Cases

Case 1.—This was a six-para aged 31, who had been married twelve years. The husband had a history of gonorrhoea. Previous deliveries were normal, and the last was nine months earlier. There had been one abortion five years previously. The patient complained of abdominal pain followed by bleeding a fortnight before admission. She was still lactating, and had had no periods since her last confinement. On vaginal examination an irregular mass was felt in the left fornix, but the uterus could not be distinguished from it. There was marked pulsation in the left fornix. At laparotomy a pelvic haematocele was found, and it was impossible to identify the left tube and ovary.

Case 2.—A four-para aged 24, married six years, whose last delivery was six months ago. Menstruation commenced two months later, but the subsequent period was a fortnight overdue. Fourteen days after this a severe attack of pain occurred in the left side, followed by continuous bleeding for six weeks. There were three recurrent attacks of acute pain. Abdominal examination disclosed a mass rising out of the pelvis and extending into the left iliac fossa equivalent in size to a sixteen-weeks' pregnancy. Per vaginam, pulsation was felt in the left fornix and an irregular-shaped swelling filled the left half of the pelvis. At operation a large haematocele was found with many intestinal adhesions. The left tube and ovary were not seen.

Case 3.—A four-para aged 33, married twelve years. The husband admitted having had gonorrhoea. Deliveries had been normal except for one abortion. The last confinement was one and a half years ago. Three weeks before admission the patient fainted as the result of a severe attack of abdominal pain. This was followed by continuous bleeding. Whilst lying in the ward prior to examination she was seized with acute abdominal pain. There was no history of menstrual irregularity. On vaginal examination the uterus was found to deviate to the right owing to a mass in the left half of the pelvis. Pulsation was present in the left fornix. At operation a large haematocele was found.

Case 4.—This patient was a nullipara aged 29, who had been married eleven years and whose husband had gonorrhoea. Menstruation had always been irregular, but the last period lasted for only one day instead of the usual week. The day after there was generalized abdominal pain, which recurred during the following week and was accompanied by a profuse blood-stained discharge. On examination the uterus was bulky and retroverted. A mass was felt in the left fornix together with pulsation. At operation a small haematocele was removed. The right ovary was buried in adhesions.

Case 5.—A five-para aged 33, married nine years. The husband had been treated for gonorrhoea. The last delivery was one and a half years ago. Three weeks before admission there was an acute attack of abdominal pain with fainting. Severe bleeding ensued. This continued for eleven days, and was followed by another bout of pain. The condition had been diagnosed as a pelvic abscess and treated conservatively. A mass was found rising out of the pelvis, and per vaginam it was filling most of the cavity. There was marked pulsation in the left fornix. When the abdomen was opened a large haematocele was seen with the appendix adherent to it. An appendicectomy was performed as well as the usual attempt at removal of as much of the blood clot as possible.

Acute Tubal Rupture with Internal Haemorrhage

Even in the acute type of ectopic gestation it is sometimes difficult to be certain of the diagnosis. Particularly is this the case in the Tropics, where patients suffer from severe degrees of anaemia due to conditions other than surgical, such as ankylostomiasis, which give the impression of sudden and excessive blood loss. In doubtful cases I would commend the simple procedure of puncture of the posterior vaginal fornix. Either a lumbar puncture needle or an ordinary wide-bore needle with syringe attached will suffice. The risk of infection is negligible, and perforation of the intestine is minimal. If there is free blood the intestines will float on the surface and so be removed from any danger of puncture by the needle. After cleansing the vaginal vault with dettol the needle is pushed through the posterior fornix into the pouch of Douglas, keeping parallel and as close to the posterior aspect of the cervix as possible. If blood is aspirated freely into the syringe the test is positive for intraperitoneal bleeding. This is a useful means of differentiating between an abdominal catastrophe due to perforation of a hollow viscus and one due to free bleeding into the pelvic cavity, as from an ectopic gestation. In Allbutt's textbook will be found the statement that "in all doubtful cases . . . recourse may be had to an exploring needle or aspirator as recommended by Sir J. Simpson and Professor Braun." In those cases in which there is much blood, and consequently irritation of the inferior surface of the diaphragm, shoulder pain may be present as demonstrated by Cope.

Case 6.—This patient was a four-para aged 34, married sixteen years, whose last pregnancy was fourteen months ago. She had had amenorrhoea for two months. The day before admission she had slight bleeding, with backache and pain in the lower abdomen. Twelve hours later there was a recurrence of bleeding and abdominal pain. The patient was very anaemic and had marked oedema of the legs. There was slight suprapubic rigidity. Per vaginam the uterus was bulky and a mass was protruding through the os. On examination of the stools ankylostoma were found. A general anaesthetic was given and the uterus explored. I was not satisfied that the case was an abortion, since the material removed on curettage lacked the typical appearance of products of conception. The posterior fornix was punctured and blood withdrawn. At laparotomy a right tubal abortion was found. There was one litre of free blood, and some of this was utilized for autotransfusion. Convalescence was uninterrupted. Pathological examination of the uterine contents showed them to be portions of a decidual cast.

The difficulty in this case lay with ankylostomiasis complicating the picture, and an unnecessary abdominal operation on a woman so infected might have proved fatal. Puncture of the posterior fornix revealed the true condition.

Case 7.—A nullipara aged 29, who had been married twelve years, had had vaginal bleeding for eight days after missing one period. Abdominal pain preceded the bleeding by about eight hours. There was a history of shoulder pain. Hypogastric rigidity was present and a small tender swelling was felt in the posterior fornix. The diagnosis was in doubt, since the patient declared that her periods were irregular and often accompanied by pain. The posterior fornix was punctured and blood aspirated. At operation the abdominal cavity contained much blood and a right tubal gestation was present. An autotransfusion of 700 c.cm. of blood was given.

Treatment

Once the diagnosis of ectopic gestation, whatever its type, is made the treatment is operation. No matter how ill or how well the patient appears there should be no alternative to this line of treatment. In all cases, provided there is no infection, the abdominal route should be employed, but where a haematocele has become infected and has developed into a pelvic abscess, then drainage through the posterior vaginal fornix should be adopted. Even if a mistake in diagnosis is made and the condition is found to be a pyosalpinx, it is more prudent to have done what may prove to be an unnecessary operation than allow an ectopic gestation to remain untreated.

Pelvic Haematocele.—In the past palliative treatment was strongly advocated in those cases in which the haematocele was small. It was suggested that the mass was absorbed *in situ*. One has only, at operation, to look carefully at the capsule to realize how thick it is and what a length of time must be required before absorption is complete. I am of the opinion that all cases should be dealt with by operation. The objections to conservative treatment are: (1) the interminable length of convalescence and invalidism before absorption is complete; (2) the persistence of uterine bleeding, either continuous or intermittent, which will induce anaemia; (3) the constant pain, which at times is punctuated by acute attacks; (4) the risk of infection and formation of a pelvic abscess. At operation as much of the blood clot as possible should be removed. If the capsule is found to be adherent to the bowel no attempt should be made to separate it. When the appendix is involved in the mass an appendicectomy should be done. Only in the presence of definite infection or where there is persistent oozing from raw surfaces should a drainage tube be inserted.

Acute Tubal Rupture.—The value of autotransfusion requires emphasis. In some gynaecological clinics it is a routine procedure, and even in the case of fibroids removed by hysterectomy Wallingford (1937) is now conserving the blood and returning it intravenously to the patient. It is obvious that in the presence of infection one would never employ this method. The beneficial result of the transfusion is remarkable in cases which appear moribund, and convalescence is more rapid. Care must be taken to filter the blood through several layers of fine gauze. The "citrate" method has been used in all cases.

Summary

1. In the diagnosis of pelvic haematocele the history of recurrent attacks of low abdominal pain accompanied

by periodic or continuous uterine bleeding is very significant. Pulsation in one or other fornix confirms the diagnosis.

2. In acute tubal rupture if there is doubt as to the presence of free blood in the pelvic cavity, puncture of the posterior fornix is a useful accessory means of diagnosis.

3. Operation should be resorted to in all cases, no matter how small the haematocele. If possible, drainage should be avoided. In the acute case where there is free intraperitoneal bleeding and no infection autotransfusion should be performed during the operation.

I wish to thank the Director of Medical Services for permission to publish these cases and for the clinical facilities he has given me.

Clinical Memoranda

Prostigmin in Paralytic Ileus

The points of interest in regard to the case reported appear to be: (1) Cracked ice should not be given postoperatively unless there is adequate supervision to ensure that the melted ice is not swallowed. (2) Atropine brakes the action of prostigmin, and is thus better avoided. (3) There was no alteration in the pulse and respiration as the result of the administration of 2.5 mg. of the drug in one injection.

The patient was a man aged 62 weighing 17 stone, who was operated on for intermittent left renal colic. A lower polar aberrant vessel was divided and the pelvi-ureteral junction straightened over an inlying catheter splint. The anaesthetic was 15 c.cm. of a solution of 1 in 1,500 percaine intrathecally, supplemented by gas and oxygen.

No purgatives or enemas were used in the pre-operative preparation, and the bowels had acted normally on the morning of the operation. During the first twenty-four hours following his return to bed nothing was given by the mouth, but four pints of 5 per cent. glucose in normal saline were injected intravenously. Cracked ice was sucked by the patient, and it appeared afterwards that he had swallowed large quantities of the melted ice. This was the probable cause of his subsequent trouble. Flatus was passed within a few hours of his return to bed, but on the second day distension had set in. No relief was obtained from enemas of all varieties, including ox-bile and molasses. Pituitrin had no effect. Acetylcholine was given in 0.1 gramme doses every two hours without result. By the third day regurgitant vomiting had begun, and upper abdominal distension was marked. At noon on this day 5 ampoules, each of 1 c.cm. prostigmin (2.5 mg.) were injected subcutaneously together with 1/100 grain of atropine sulphate. Colic and sweating occurred within thirty minutes, and a fair amount of faeces and flatus was passed. The upper abdominal distension remained, and the action of the drug exhausted itself within fifteen minutes.

By 7 o'clock in the evening distension had increased, though the pulse was stronger. Another 5 c.cm. of prostigmin was injected. This had no effect for twenty minutes. At the end of that time sweating and violent colic commenced, and after a few minutes large quantities of faeces and flatus were passed. The emptying of the bowels continued for some hours, by which time the abdomen was flat. The bowels required some adjustment for the next few days, but convalescence was on the whole uneventful.

Similar fortunate experiences resulting from the use of large single doses of prostigmin have been recorded by some Continental writers, and by W. E. David (*Lancet*, May 11, 1935) in England.

Johannesburg. R. CAMPBELL BEGG.

Parkinsonism following Peripheral Trauma

The case recently reported (Walker, 1937) prompts me to record one other.

In January, 1916, a man aged 27 sustained a gunshot wound in the right forearm while serving in Mesopotamia. He shows the scar of entry about an inch proximal to the wrist-joint, and a two-inch scar about six inches above it, where the bullet was partly removed. A piece of shot is still palpable.

He was sent to India, where he did nothing for twelve months, and was then posted as band storeman and as unfit for active service because he could not use his arm. The ring finger of his right hand had twitched since the injury—the tremors were worse when not inhibited by his active consciousness of them; he had some pain and stiffness (hypertonus) and loss of power in his right hand. In February, 1919, he was demobilized, and this disability was still present.

In July, 1919, he was appointed policeman at Dover Marine Station, which post he held for twelve years. In 1924 the twitching spread to his right hand; he could still write, but only slowly. In 1928 he complained of stiffness and loss of power in his right knee (hypertonus). In 1929 the sensation of "pins and needles" occurred in his hand and arm; about this time his wife noticed that he held himself very stiffly and that his arms were kept in a flexed position. She also stated that they changed houses in that year, and that he used to run on the path uphill to the house, as he found this easier than walking: he tended to drag his foot (hypertonus). The tremors got steadily worse, and because of this he lost his position, as he could neither write nor walk properly. *From 1931 to 1934* he was keeper at a level crossing, his wife performing most of his duties. In the latter year he was dismissed owing to incapacity for work.

In 1934 my notes stated that he presented the full clinical picture of the Parkinsonian syndrome: tremors no longer unilateral, blank expression, forward gait and posture, and dry flat monotone. In addition there were signs that neuritis was affecting his radial, ulnar, and median nerves. *He is going slowly downhill*, and one of his most prominent symptoms is his frequent desire to be moved in bed—a symptom quoted by some authorities.

COMMENTARY

This case shows all the characteristics of Naville and de Morsier (1932).

1. In the interval between the injury and the full development of the Parkinsonian syndrome the injured limb remains weak, painful, and subject to sensory disturbances.

2. Tremors and hypertonus almost always appear on the injured side.

3. The syndrome becomes manifest on the injured side.

4. Mental changes are absent.

I regret to say that my representation and that of the other two doctors who had attended him met with no success from the Ministry of Pensions in 1934.

Reviews

AMERICAN MEDICINE

Physicians and Medical Care. By Esther Lucile Brown. (Pp. 202. 75 cents.) New York: Russell Sage Foundation. 1937.

American Medicine. Expert Testimony Out of Court. Two volumes. (Pp. 1,435; 3.50 dollars the set.) New York: The American Foundation. 1937.

Here are two books dealing with much the same field, the one perhaps unduly small, the other unnecessarily large. The field that they cover is American medical education and the conditions and methods of American medical practice; but it may not be really fair to compare them, in the matter of size at all events, since they differ radically in presentation and object. The smaller book, admirable in format in every respect except in the absence of an index, is by Esther Lucile Brown of the Department of Statistics of the Russell Sage Foundation, and is issued by that Foundation as one of a series of monographs dealing with the present status of certain established or emerging professions in the United States, under the title *Physicians and Medical Care.* The larger work, entitled *American Medicine,* is published in two volumes, not very easy or convenient to handle though well printed, by the American Foundation, with the qualified co-operation of a formidable medical advisory committee, again as one of a series of studies in government. This place of each of these books in its series is of some importance to remember as it has determined to a material degree the method of assembling and presenting the content, as well as the volume of that content itself. Each book deals entirely with American medicine and conditions, without any reference to professional education and conditions of practice elsewhere; nevertheless most of the problems discussed are the same as, or very similar to, those of this country and have a direct and important relationship thereto. Each book, in its particular way, is a valuable contribution to knowledge of fact and formation of opinion which no one interested in the subjects dealt with can well afford to neglect.

In some two hundred easily read pages *Physicians and Medical Care* presents a summary, compact, comprehensive, and fairly complete, of the conditions of medical education and practice in the United States and of the organization of the medical profession in that country. Each section leads up to a description of the present-day situation by the historical method. This approach through history is not at all laboured, but is essential to the understanding of the position to-day, and is illuminating in many ways. It shows how recent and how rapid have been the improvements and reforms which have brought American medicine to a relatively favourable phase, and explains alike some of the crudities which, compared with this country, still seem to remain in its organization and practice, the character of the needs of those who entered the profession at an earlier date, and the relative timidity of outlook in the presence of urgent, peculiar, and difficult problems. With regard to this last it is said that "medicine is one aspect of the general civilization of a country. Its quantity and quality form an index of the level of that civilization. Recent changes in the nature and distribution of health service reflect diverse alterations in the political, economic, and philosophical concepts of our national life." This important truth is often forgotten. The several sections of the book deal with medical education, with professional associations, with the number, distribution, and income of practitioners, with the new forms of medical service now in the experimental stage—whether under the auspices of industry, of hospitals, or of voluntary medical groups—and with the question of providing adequate medical care for all the people either by a health insurance system or by State Medicine. All these matters are presented in an admirable and very effective way.

The method adopted in *American Medicine* offers a complete contrast to this, but, of its kind, the work is almost equally well, if too abundantly, done. The favourite American practice of a questionary sent to a selected and supposedly representative clientele was chosen. The main questions related to the adequacy and availability of medical care, to the general principles which should determine its organization, to the nature of the education which would produce the best supply, to the limits of specialization and the conditions which should control it, to group practice, to the proper place of hospitals, to public health organization, to socialized State Medicine, and to voluntary or compulsory health insurance or to what is called "limited State Medicine" as alternatives thereto. This last envisages "the evolutionary extension of the present functioning of government in the field of health and medical care," and "an integration of the public health services with private practice, an intimate understanding and co-operative development of State Medicine and private medicine, neither of which can apparently reach its ultimate development alone." Some of this is a little vague, and the method by question is itself of doubtful value, but in this inquiry it seems to have been relatively well used. As might be expected the answers were voluminous and of varied value. In the several sections of the book a vast number of extracts from these answers have been set out. This has been done with skill, with impartiality, and in a manner to make them as effectively useful to the inquirer as possible. As is said on behalf of the Governing Committee of the Foundation in an introduction: "Some have worked out their thoughts with labour, have tested them by their experience, subjected them to every challenge they know, and even then offer them tentatively. Others with no great amount of thought have stated emotional preferences with great vehemence." But, as is also said, "the interest and purpose of this report is to illuminate and not to prove. . . . We have been aiming at an analysis of the situation that would take all, and not merely some, of the pertinent factors into account. We have not, at this point, been concerned to find solutions for the problem or for any particular part of it. On the other hand, we have wanted to etch in the present picture fully, and, by demonstrating its complexity, avoid over-simplification in the application of remedies." The result is two volumes of very great interest, offering abundant opportunity for selection; not to be read through, but highly valuable for reference both as containing many wise views and conclusions and as presenting a suggestive picture of American medical practice.

PAIN IN THE KIDNEY

Kidney Pain. Its Causation and Treatment. By J. Leon Jona, D.Sc., M.D., M.S., F.R.A.C.S., M.C.O.G. (Pp. 94; 61 figures. 7s. 6d.) London: J. and A. Churchill. 1937.

The mechanism of kidney pain has been investigated by Dr. Leon Jona, who became interested in the subject by observing the renal pelvis when distended by opaque material on the *x*-ray screen in cases he had under treat-

ment at the Women's Hospital in Melbourne. Dr. Jona was led to his problem by considering that the pelvis of the kidney was a hollow viscus with a nerve supply comparable with that of other organs in the abdomen. He has made numerous observations by pyeloscopy, and by attaching a recording manometer to the ureteric catheter he has been able to measure and record the fluctuations of pressure in the renal pelvis under physiological conditions and under the influence of drugs. He has extended his work to dogs and has compiled a useful introduction to a newly explored field of pathology.

The kidney pelvis and ureter form a system of two sets of hollow chambers, the calyces and infundibulum, and a series of muscular contractile tubes, the collecting tubules, the communicating channels between calyces and infundibulum, and the ureter. The pressure record of the normal renal pelvis shows a series of large waves representing the contractions of the infundibulum, on which are superimposed small waves from contractions of the calyces. The general pressure can be affected by posture and by altering the intra-abdominal pressure; adrenaline and pituitrin cause contraction of the renal pelvis and atropine relaxes it; caffeine contracts, ergot relaxes it. The author has noted various forms of dysfunction of the renal pelvis apart from stone, and suggests methods of treatment. The main classifications are interference with the neuromuscular mechanism, pathological conditions in the urine or urinary tract, reflex effects from organs with related nerve supply, and general diseased states of the body. Spasm of the pelvis and ureter is generally relieved by quinine given in doses of 5 grains three times a day for a few days; atropine may be used in addition. Atony is generally relieved by eserine, strychnine, or morphine. The author has drawn largely from general physiology in putting together this interesting little book.

MEDICAL STATISTICS

Principles of Medical Statistics. By A. Bradford Hill, D.Sc., Ph.D. (Pp. 171; 6s. net.) London: The Lancet, Ltd. 1937.

It is not without significance that both in the foreword, contributed by the Editor of the *Lancet*, in whose columns the subject-matter first appeared, and in the author's preface to this book, the importance of statistical method in *clinical* work is stressed.

That knowledge of and even training in statistical methods are necessary for members of the public health service has long been admitted, but appreciation of the value of arithmetic guided by logic—a fairly accurate definition of statistical method—in clinical work has been slow. There are two reasons for this. The first is that the assembling of clinical or pathological data implies knowledge and experience of a special kind which have involved years of training, and it is natural that the investigator should believe that this, the first step, is the most important, as of course it is. The other reason is that to become an expert statistician, in the technical sense, requires as much training as to become an expert clinician or pathologist. That the particular qualities characterizing the expert physician and the expert statistician might be combined in the same individual is possible; but it is a possibility not likely to be realized very often. If the clinical investigator must choose between clinical and statistical learning, plainly it is his statistical education which must be economized. That, however, does not mean that he can dispense with all statistical knowledge. A Jack of all trades and master of none is no doubt a sorry sight; an even sorrier is he who knows more and more of less and less. The youth who studies French with the ambition of being mistaken for a Frenchman is foolishly optimistic; he who declines to study French at all, on the ground that he will never speak French like a Frenchman, is not a wise man. A knowledge of French considerably short of Voltaire's has its value.

This reflection is relevant to the present subject. Actually, as editors know to their cost, statistical errors are often quite elementary violations of fundamental logical principles, overlooked because of the complexity of the details. In theory nobody needs to go to school with a statistician to learn that in a controlled experiment the "treated" and "untreated" groups should be *in pari materia*. Nobody needs a statistician to tell him that before one draws some inference from a difference between the recorded rates of mortality of a disease, or between the frequency of some necropsy finding in different places or at different times, we must be satisfied that the times and places are fairly comparable. But, in practice, unless one does acquire a certain amount of experience in detecting such errors and some knowledge of the ways in which they may be avoided, these elementary mistakes will continue to be made.

The special merit of Dr. Bradford Hill's book is that he gives much of his space to the illustrations of the kind of mistake which is commonly made. The professional statistician "has no burning desire to be called in as an expert witness at the conclusion of the case for the plaintiff (on a subject-matter he may not fully understand) to say that this is 'significant' and that is, statistically speaking, nonsense. It even requires some equanimity to be unmoved when he is transferred to the dock on a charge of being merely an armchair critic or a confirmed sceptic. In other words, neither party to the transaction is particularly happy." As the author says, there is only one way of escape. "The worker in medical problems, in the field of clinical as well as preventive medicine, must *himself* know something of statistical technique, both in experimental arrangements and in the interpretation of figures."

Dr. Bradford Hill has provided the medical reader with the means of self-instruction. The book is short, lucid, and practical. Anybody who has read it carefully, with a pencil and a piece of paper beside him which he has used, will not be in a position to criticize the methods of Karl Pearson or to enter the lists with Professor R. A. Fisher; but he will certainly have learned how to avoid many errors and how to present the conclusions of his researches in a logical way.

GROUNDWORK OF CLINICAL NEUROLOGY

The Basis of Clinical Neurology. The Anatomy and Physiology of the Nervous System in Their Application to Clinical Neurology. By Samuel Brock, M.D. (Pp. 354; 72 figures. 21s.) London: Baillière, Tindall and Cox. 1937.

"A successful approach to the understanding of disease of the nervous system requires a thorough knowledge of neuro-anatomy and neurophysiology." With this axiom Dr. Samuel Brock introduces his *Basis of Clinical Neurology*, in which he succeeds in compressing the essentials of this knowledge in a very readable form. The chief difficulty in a book of this kind is that the physiology of the nervous system, even more than that of other systems, is constantly developing, and with this growth of knowledge old theories and even some old observations have been put on the scrapheap. Dr. Brock meets this difficulty by giving short summaries of the most recent work on various questions, leaving the student to formu-

late his own views from the divergent and sometimes discordant theories and observations of different workers. This indeed seems to be the most satisfactory method of presenting the subject, and the author has shown wisdom and restraint in leaving questions open when a dogmatic statement or prejudice in favour of one theory might well prove erroneous. This applies especially to such questions as sensation, aphasia and apraxia, and the various problems arising in vascular disease of the brain. In dealing with some subjects which lie on the borderland between physiology and pathology, such as the healing of nerves after division, the causation of trophic ulcers and Charcot joints, and the mechanism of hydrocephalus, to mention only a few, the author's touch is less sure, and statements and suggestions are made which cannot easily be brought into line with the known facts. These subjects, by their nature, do not admit of a simple physiological explanation, and for that reason might well have been omitted from a book of this kind. But when he keeps more strictly to anatomy and physiology little fault can be found with Dr. Brock's book, which shows wide knowledge, care in choice of material, and skill in its presentation.

ELEMENTS OF HYGIENE

A Handbook of Hygiene for Students and Teachers. By Cyril G. Eastwood, B.Sc., M.B., Ch.B., M.R.C.S., L.R.C.P., D.P.H. (Pp. 358; 151 figures. 6s.) London: E. Arnold and Co. 1936.

Dr. Cyril Eastwood's handbook of hygiene is based upon his course of lectures in elementary physiology and hygiene in the University of Leeds and at the City of Leeds Training College, and may therefore justly claim to have in some measure already stood the test of experience. The aim of the author is to maintain the physiological approach from which the advance is made to hygiene and its applications. The six parts of the book are entitled: Biological and Physiological Foundations; Nutrition and Dietetics; Hygiene of Children; Diseases of Children; Hygiene of the School; and Hygiene and Education. The information supplied appears in general well suited to those for whom it is intended, though the ventilating system of the House of Commons is, we think, not one which should be revealed to the simple-minded. In any case it is some years now since the fire in the Clock Tower was replaced by a fan.

Notes on Books

In their small book, *Emanotherapy* (Baillière, Tindall and Cox, 7s. 6d.) Dr. F. HOWARD HUMPHRIS and Dr. LEONARD WILLIAMS set out to convey clear information on a useful therapeutic agent, and to indicate those diseases in which emanotherapy has been found of service. The preface expresses a hope that this book may fill a niche in the literature of little-known remedies, and the authors make acknowledgement to friends on the Continent and in England for help in the attainment of the knowledge which they here summarize.

The late Dr. T. D. Savill's *System of Clinical Medicine* first appeared in 1905 and now reaches its tenth edition under the editorship of Dr. AGNES SAVILL and Dr. E. C. WARNER (Edward Arnold, 28s.). This work differs from current medical textbooks in that it approaches medicine from the point of view of symptomatology, a method which the author believed would be of great help to the senior student and the practitioner. Dr. Savill's original introductory chapter, which gives a clear explanation of his aim, has been retained in this as in every previous edition.

Preparations and Appliances

A CHEAP DEVICE FOR POSTURAL DRAINAGE OF THE LUNGS

Mr. ROBIN PILCHER (University College Hospital) writes: Bedsteads designed for postural drainage may be regarded as an unjustifiable expense in small hospitals where they are rarely required, and for hospital patients continuing postural treatment at home their cost is prohibitive. The device illustrated here offers some of the advantages of the special bedsteads, costs little, and can be made by anyone with a little knowledge of joinery. It consists of two wooden platforms of the same size as the bedstead on which they are to rest. The lower is rigid, the upper is made in two halves hinged to a central transverse bar, and can be raised to the form of a wedge by a block placed beneath it. The block slides in a chamfered slot on the lower platform. The height of the wedge can be varied by using blocks of different sizes or by introducing boards between the block and the transverse bar of the upper platform. This bar projects beyond the edges of the platform, its ends being shaped to form handles by which the platform can be raised for the introduction or removal of the block without disturbing the bedding or the patient. The actual dimensions depend on the size of bedstead to be used, but a useful height for the block is 10 inches. It has been used at this hospital in the treatment of suppurative conditions of the lungs, and within the limitations imposed by its simple structure has given satisfactory results. The first model was made by Mr. H. Roberts, technical assistant to the Surgical Unit, to whom I am also indebted for the drawings.

DIETETIC MALNUTRITION

Graham Lusk, in his standard work on *The Science of Nutrition*, defines "nutrition" as "the sum of the processes concerned in the growth, maintenance and repair of the living body as a whole or of its constituent parts." In these days, when the words "nutrition" and "malnutrition" are so loosely used, it is necessary to have this, or some equally good, definition clearly in mind, for then only can it be understood why it is that perfect nutrition is an indispensable condition for the maintenance of health, and why it is that imperfect nutrition (malnutrition) is a dominant factor in the production of ill-health. The recently published and final report of the Mixed Committee of the League of Nations on *The Relation of Nutrition to Health, Agriculture and Economic Policy*[1] does not deal with nutrition as so defined. It is not concerned with the processes involved in nutrition nor with their disturbance in causing imperfect nutrition. It is not concerned with imbalance or excesses of food constituents, with over-eating or with disuse of the adaptive functions. Such causes of imperfect nutrition are outside its scope. Nevertheless, throughout its pages the word "nutrition" is frequently used when "food" is meant and would have served the purpose better.

The report deals, in fact, with the relation of food to nutrition, health, agriculture and economic policy. It is a treatise on "dietetic malnutrition": a state of ill-health widespread in its distribution, having a great variety of symptoms, due usually to poverty but often to ignorance, and preventable only by reorganization of our ways of life—social, agricultural, and economic—so as to ensure for everyone a diet that will satisfy physiological needs. The report is an authoritative and comprehensive contribution to this the most important aspect of the nutrition problem—a problem of world-wide urgency. It deals first with the principles of correct feeding: principles, it may be assumed, well known to readers of this *Journal*. The symptoms of dietetic malnutrition are mentioned here and there throughout its pages, chiefly in those of Part II. They indicate the extent to which the body as a whole and its constituent parts may be disturbed in structure or in function by the habitual use of improperly constituted food; the part of the body affected and the severity of its disturbance depending on the kind and degree of the food fault or faults, the age and sex of the subject, the climatic conditions under which he lives, and the work he has to do. There are symptoms referable to the skin, the bones and teeth, the eyes, ears and nose, the gums, mouth, tongue and pharynx, the gastro-intestinal tract and its associated organs, the endocrine glands, the heart, blood vessels and blood, the nervous and reproductive systems, the lungs, kidneys, and bladder—and, to the mind. Some of these symptoms make up the clinical pictures of disease-entities, known to medicine by special names and catalogued in the *Nomenclature of Diseases* under this or that system of the body. But some, such as subnormal growth in height or weight, poor physique, lack of vitality and activity, chronic fatigue, headache, insomnia or disturbed sleep, irritability, nervousness, apprehension, vague aches and pains, may be the evidence of undefined general ill-health to which no diagnostic label, other than that of malnutrition, can be attached. Further, faulty nutrition, consequent on the habitual use of faulty food, lowers the resistance of the body to infection; these two combining to produce a great variety of maladies.

This much and more may be gleaned from the report, for in following the course of dietetic malnutrition throughout life it provides information of profound interest and importance. Because of the substitution of artificial feeding for mother's milk, infants become subject to gastro-intestinal and pulmonary disease to which they frequently succumb. The mortality rate among infants attending a welfare centre in Chicago was found to be 8.4 per cent. when they were artificially fed, against 0.15 per cent. when they were wholly breast-fed, or fifty-six times greater. Anaemia, imperfect calcification of the developing teeth, imperfect growth of the jaws, rickets, osteoporosis, and poor growth and condition of the body as a whole are other symptoms of malnutrition in infants. In early childhood malformations of the bones, dental defects, and abnormalities of the pharynx are alarmingly common:

> "In a recent inquiry (1931) in London schools it was revealed that among children of 5 years of age there were 67 to 88 per cent. of cases of abnormalities of the bones, 67 to 82 per cent. (according to the gravity of the symptoms) of cases of adenoids, enlarged and septic tonsils, and other disorders of the pharynx, 88 to 93 per cent. having badly formed or decayed teeth. Although there is no proof that all these defects could have been avoided by improved feeding there is good evidence that many would not have developed under such conditions."

There is, however, the best of evidence—that given by Miss Margaret McMillan in her book, *The*

[1] Allen and Unwin, 40, Museum Street, London, W.C.1. 1937. (Pp. 327. Price 7s. 6d.)

Nursery School (1931)—that by proper nurture, which includes perfect nutrition as above defined, all or almost all of them can be avoided. Consequent on malnutrition, children of this age have a lowered resistance to such diseases as measles, scarlet fever, bronchopneumonia, middle-ear disease, and nephritis. "Below the age of 3 years measles is a particularly deadly disease, and there is suggestive, but not conclusive, evidence that the high mortality rate at this and older ages could be reduced by better nutrition of such children." The wise physician and the prudent medical officer of health will be content to act on the suggestive, and not to wait for the conclusive, evidence. Thus it is that "in the early years of school life young children are already 'damaged goods'"—a phrase in which there is the echo of Miss McMillan's voice. "They frequently show evidence of previous defective feeding and lack of care in deformity of the bones of the limbs, chest, and head, in bad dental structure often associated with decay, in deafness to a greater or less degree, in running ears, septic tonsils, and adenoids. . . . These indications of disease are not generally, from the present medical point of view, regarded as evidence of malnutrition . . . although this is probable." They are certainly evidence of malnurture.

"Malnutrition is usually diagnosed in school children on the basis of subnormal growth and weight and general sickly appearance of the child. Nothing is more important than that a new attitude should be adopted towards the problem, for whereas such results of improper feeding as subnormal growth and weight and undefined general ill-health can usually be rapidly improved by better feeding conditions the more chronic conditions due to earlier defective dieting cannot be so easily remedied, but continue to act as a handicap throughout life. . . . Prevention rather than treatment of disease must be more and more emphatically stressed and, so far as this can be procured by better feeding, this ought to be done."

In this connexion attention may be drawn to the Committee's recommendation of the "Oslo breakfast" as a method of improving the nutrition of school children—a recommendation we heartily endorse. There is suggestive evidence, too, that increased tendency to fractures, to rheumatism and rheumatic conditions with their tragic associates—chorea and heart disease—may have a malnutritional basis. So from infancy and childhood through adolescence to adult life malnutrition leaves its trail of morbidity. Amongst adults every fresh inquiry in town and country reveals evidence of patent or latent malnutrition. We may conclude this survey, though leaving much unsaid, with a reference to latent malnutrition of dietetic origin:

"Many of the well recognized 'deficiency diseases'—such as scurvy, rickets, beri-beri, pellagra—are caused by severe, prolonged deficiency of one or other of the essential protective vitamins. Except for rickets they are, fortunately, of relatively rare occurrence in temperate regions, and their full manifestation can usually be prevented by a minimal intake of the appropriate protective factors. Much more common are the latent states of malnutrition which may give rise to no visible disease—states which might be called pre-scurvy, pre-rickets and pre-osteophorosis, pre-pellagra, pre-beri-beri, pre-caries, and the formation of teeth of imperfect architecture. The opportunity that lies before the science of preventive nutritional medicine rests upon the knowledge that these states exist and upon the proof of the necessity for striving after *optimum* nutrition rather than *minimum* nutrition."

There is in all countries, the report assures us, a tendency towards better nutrition, consequent on the use of better food. But the movement is checked and obstructed at certain points, and requires to be directed and accelerated. Such improvement as has taken place is due in part to a better understanding of dietary needs, in part to a general increase of income and prosperity and to ease of transport, and in part to improvements in the methods of production and distribution of agricultural products. But poverty, ignorance and indifference remain formidable obstacles to progress. The disparity between food prices and income increases the difficulty experienced by the poorer sections of the community in obtaining an adequate supply of proper foods. Consequently, "millions of people in all parts of the globe are either suffering from inadequate physical development or from disease due to malnutrition or are living in a state of subnormal health which could be improved if they consumed more or different food. That this situation can exist in a world in which agricultural resources are so abundant and the arts of agriculture have been so improved that supply frequently tends to outstrip effective demand remains an outstanding challenge to constructive statesmanship and international co-operation." How the Committee proposes to relieve, if not to resolve, this tragic situation we must leave the reader to learn for himself by a study of this most valuable report.

HAEMOPHILIA

Haemophilia is nowadays one of the most familiar diseases, not only to medical men but also to the general public, which finds it a frequent topic in the daily press and an occasional theme of detective stories. It is therefore interesting to be reminded that Dr. J. C. Otto's "Account of an Haemorrhagic Disposition Existing in Certain Families," the first adequate description of the disease, was published in 1803, and that as late as 1893 A. E. Wright, happily still at work in medicine, brought out the fact that the clotting time of haemophilic blood

was prolonged. These facts are taken from a monograph on the clinical and genetic aspects of haemophilia by Dr. Carroll Birch, based on a personal study of ninety-eight cases and seventy-five families in the neighbourhood of Chicago.[1] It is a fascinating study, from which the most expert will learn something fresh about haemophilia. The series of photographs, portraying haemophiliacs and their lesions at various ages, describes more forcibly than words the relentless tragedy of the disease, and the genealogical charts show how the tragedy continues to be played out and to wring the hearts of successive generations.

The three outstanding findings in haemophilia are said to be a history of habitual and immoderate haemorrhage in males, beginning early in life; prolongation of the coagulation time of the blood; and heredity. The coagulation time of the blood undergoes considerable spontaneous variations, ignorance of which, coupled with premature publication, is responsible for the large numbers of ephemeral cures for haemophilia. The coagulation time tends to be at the highest in the spring. In the worst phases the bleeding time may be prolonged and a few petechiae may appear in the skin, but these phenomena are unusual and the blood platelets and retraction of the clot are normal. Haemorrhage from trauma and haemarthrosis are the characteristic lesions, but spontaneous and visceral haemorrhages, such as epistaxis, haematuria, gastro-intestinal bleeding, and haemorrhage into the central nervous system, occur more often than is generally realized. The prevalent impression that haemophiliacs improve greatly at or after adolescence is erroneous. None but the very mildest cases survive, for 57 per cent. die during the first five years of life and 95 per cent. by the age of 40. In adult life the hazards of the teething process are over, exposure to physical trauma is less after the game-playing period is past, and the patient is usually limited willy-nilly in his activities by crippling deformities.

In this large series of cases and family trees there was no single instance of haemophilia in the female. On the other hand, the statement sometimes made that haemophilia is never transmitted through the male is quite unfounded, and such transmission is shown in eleven of the seventy-five genealogical charts. It is uncommon because few haemophiliacs live long enough to have children. Children of haemophiliacs do not show the defect. Their sons are normal and the descendants of these sons are normal; their daughters, however, all carry the trait, and theoretically 50 per cent. of the daughters' sons should have haemophilia. Thus the only members of a haemophilic family who can safely beget children are the unaffected males. "The life of a haemophiliac and that of his family, especially his mother, are so tragic that it certainly behooves those who may transmit the disease to refrain from having offspring."

[1] *Hemophilia: Clinical and Genetic Aspects.* By Carroll LaFleur Birch, M.D. University of Illinois Press. (2 dollars.)

THE LEAGUE AND HOUSING

The League of Nations, through a commission of its Health Organization, is turning its attention to housing, the importance of which from the League's point of view became evident during the European Conference on Rural Hygiene in 1931. The programme of the commission covers what is rather clumsily described as the "hygiene of the environmental conditions in dwellings," meaning the temperature, freshness, humidity, and movement of the air, also noise, sun exposure, natural and artificial lighting, and population density. Campaigns against air pollution will also be considered, together with methods of water supply and sewage and waste disposal and the administrative and legislative aspects of housing hygiene. National committees have been formed in seven countries, including the United Kingdom, to study the provisions for hygienic housing and to establish co-operation in the international sphere. Two of the committees into which the commission has divided have so far made reports. One of these, under the chairmanship of Dr. G. W. C. Kaye, superintendent of the Physics Department of the National Physical Laboratory, has been investigating the subject of noise from the point of view of housing. A number of details are given of measures which might be recommended for dealing with the noise problem, some of them involving only minor expenditure, such as good internal planning of the dwelling, the choice of the quietest rooms as bedrooms, the cultivation of public opinion regarding the use of powerful wireless sets and other sources of disturbing sounds, and the use of suitable ear stops. Other measures call for expenditure by individuals or public authorities, as, for instance, town planning, with a view to locating dwellings in quiet areas; co-operation between local authorities and industrialists in the lay-out of noisy plant; reduction of noise at the source, as by the use of silencers on motor vehicles; and insulation of dwellings against external noise by double windows, partition walls, resilient floor coverings, and sound-absorbent materials for ventilating ducts and the like. One matter to which the report draws attention is the installation of quiet sanitary appliances. In some modern flats the only sound which comes from the adjoining flat is that of the cisterns, but it can be most penetrating, aggressive, and disturbing. The committee states that experience in many countries has already shown that the measures it advocates may be successfully employed to lessen the nuisance of noise in many situations. Another committee which has reported has been concerned with questions of temperature and air purity in dwellings. This committee, which sat under Dr. C. E. A. Winslow, professor of

public health, Yale School of Medicine, found itself less able to reach conclusive results, largely owing to the fact that on the standards of temperature and humidity very different views are held in different countries, deriving from differences in climate and national custom. Thus British authorities are in favour of a lower range of temperature for the home than their American colleagues, although their views on minimum air movement are the same. Again, while British and American hygienists prefer very slight air movement, in France, due perhaps again to long-standing custom, the aim is to prevent any air movement at all, however slow, in the immediate vicinity of the individual, as British travellers in French trains know to their cost. Again, the standards applied in different countries for the floor space or cubic content of family dwellings vary on account of differences in national customs and standards of living. At present this part of the work does not seem to have got beyond the stage of vague generalities, but the commission is only at the threshold of its task.

RECENT WORK IN BIOCHEMISTRY

Launched five years ago as a comprehensive work under the direction of a distinguished editorial committee and with eminent contributors, the *Annual Review of Biochemistry* was everywhere accorded an enthusiastic welcome by biochemists. It fulfilled a most urgent need in supplying an authoritative account, by experts in their respective fields, of the major contributions made to the progress of the science in the preceding year. With further appearances it has become recognized as the most valuable single volume on biochemistry published in the course of the year. The sixth volume[1] upholds the standard of excellence set by its predecessors. The general editorial policy remains practically unaltered, but if there is any slight tendency to change it is that the several contributors, particularly those dealing with the most rapidly expanding branches, do not attempt quite so much in the way of an all-embracing survey, but rather restrict themselves to those aspects of the newer work with which they have become best acquainted. This has the advantage of making the reviews more authoritative, though it appears at first as if it might lead to some important omissions. This risk is obviated, however, by the policy of changing the personnel of the team from time to time, so that each section can be treated a little differently each year and new topics included. Those sections which progress at a relatively slower rate do not find a place in every volume, but only when they are deemed ripe for survey. Indeed the chief difficulty besetting the editor and his committee lies in respect of the choice of the right time for a particular section of this kind to be introduced. It is a testimony to their judgement and discrimination that no subject of fundamental importance is left for long without finding its rightful place in the *Review*. We are glad to see represented among the timely surveys on this occasion the application of microchemistry to biochemical analysis. Every branch depends to some extent upon advances in analytical methods, and none more so than the field of clinical biochemistry. This new chapter is an invaluable guide to those who constantly seek to improve upon their existing technique. As might be expected, the vitamins and hormones continue to claim a great deal of attention. In the hormone section the adrenal takes a foremost place, and the reviewers observe that ". . . this gland may occupy a position in the whole endocrine system second only in importance to that of the pituitary itself." Professor Marrian and his colleague have done a great service in pointing the way in which hitherto puzzling and apparently conflicting facts and theories of the different investigators regarding the essential activity of the cortical hormone can be brought into harmonious relation with each other. In the vitamin field much attention has been paid to the unravelling of the vitamin B_2 complex, and the nature of its various components is now much clearer. Moreover it has become possible to study vitamin B_1 deficiency on similar lines to those adopted for vitamin C—namely, by determination of the level of its urinary excretion. Enough has already been said to make it clear that no specialist in biochemistry can afford to neglect the opportunity provided by this volume to keep himself abreast of recent developments, no matter in what direction his particular interest lies. Only one final comment remains to be made. The omission of a subject index has now been rectified, but the *Review* still lacks a uniform system of references.

ORAL VACCINATION AGAINST COLDS

The medical profession is judged, as a whole and individually, largely by what it can do for minor maladies. For this reason it is all the more unfortunate that, while immense strides have been made in the treatment of many severe infections, our resources in dealing with more common and apparently trivial infective conditions have been almost stationary for many years. Failure has perhaps been most signal, because it has been notwithstanding considerable effort, in the case of the common cold. It is now known that in at least some colds a filter-passing virus is concerned, but this observation has not led to any useful advance in prevention or treatment. It seems likely that more than one cold virus exists, with the consequence that an attack by one—or any method of artificial immunization in which it might be employed—would not necessarily protect against others. Opinion has been divided for years, and still is, on the importance of bacteria in this connexion; if they are admitted to consideration this brings into the question at least six species, some of which are known to include many antigenically distinct types. It is manifestly impossible to secure specific immunity against such a multitude of potential invaders, and it is therefore not surprising that attempted prophylaxis with bacterial vaccines has had on the whole unconvincing results, although it remains a method which is widely used. There are signs that the injection of bacterial

vaccines may yield place in popularity to their administration by the mouth. For this almost too simple proceeding there is the precedent of Bezredka's antityphoid oral vaccine, and there is a certain amount of experimental evidence that the swallowing of bacteria ordinarily associated with the respiratory tract, such as the pneumococcus, does produce some degree of immunity. This method is strongly advocated by Rockwell *et al.*,[1] whose treated cases, with untreated controls, now amount to over 2,000; their present paper reports a careful study of the last 200 of these. The result of the treatment has throughout been a marked diminution in the frequency of colds and, indeed, in the number of days of illness from all causes. This study appears to have been in progress for nearly five years, and although the composition of the vaccine has been varied a good deal the results appear to have been uniformly on the favourable side. The authors' argument from the theoretical standpoint is not altogether convincing, more particularly when they invoke heterophile antigen as the clue to their success: there is really very little known about the production of resistance to one bacterial species by immunization with another, and although it is to be hoped that this very complex problem may prove capable of solution on some such lines non-specific immunization is still in its earliest infancy so far as any genuine knowledge of its *modus operandi* is concerned. Nevertheless this method seems worthy of more extended study; it has the advantages of safety and simplicity, and can be repeated frequently with little trouble to the patient and none to anyone else, which should at least secure it a full and fair trial.

PHYSICAL ASPECTS OF RADIUM AND RADON THERAPY

An excellent little pamphlet on this subject has been issued by the Health Department of the Australian Commonwealth.[2] It is written by Dr. C. E. Eddy and Mr. T. H. Oddie of the Government *x*-ray and radium laboratories at the University of Melbourne, and in very brief compass epitomizes the main physical principles which are the basis of radium therapy. A section on the physics of radio-activity is followed by a description of the various forms of radium applicator, and this in turn by an account of the properties and method of extraction of radon, and its mounting for therapeutic use. Tables are given showing the rates of growth and decay of radium emanation, and the rise of gamma ray activity after the containers have been filled. Examples of the calculations involved in estimating the content of radon containers are followed by an illustrated description of the methods of filling them. The advantages and disadvantages of radium as compared with radon are briefly and clearly set forth, and the pamphlet ends with an account of the all-important question of gamma-ray dosimetry. A short but comprehensive and representative bibliography of the various questions considered indicates the lines upon which more extensive reading may most profitably be conducted. The foreword, which is contributed by the Director-General of Health, emphasizes the need for physical and clinical co-operation, and the opening paragraph may be quoted with advantage:

"The efficient practice of radiology is a science in which the skill, judgement, and experience of the clinician require to be supplemented by exact measurements of a physical nature involving the use of delicate physical instruments and the services of a specialized physical laboratory. Only when the application of radiation in the treatment of human disease is placed on a basis of exact scientific measurement can this remedy be safely and effectively administered. Because of this, the radiotherapist must possess a knowledge of the physical aspects, not only in order to understand clearly the technical literature, but to enable him to assess the relative significance of the various therapeutic techniques."

Practising radiotherapists as well as laboratory workers will find this booklet a useful and convenient source of reference; to those who are beginning the study of radiotherapeutics it will form an excellent introduction to some of the fundamental principles upon which a very complicated and difficult study is based.

SULPHANILAMIDE IN URINARY INFECTIONS

In the therapeutic advances of the past few years the urinary tract has had its full share of advantage and more. The ketogenic diet was the first innovation which proved capable of really sterilizing the urinary tract within a few days; it was succeeded shortly by mandelic acid, which proved even more effective and much easier to administer, although the control of urinary *p*H and the nausea sometimes occasioned by medicaments required for reducing this are still practical difficulties of some consequence. If therapeutic progress had stopped here it would still be reckoned as one of the most striking achievements of modern medicine. The contrast is complete between the regular and rapid effect of this treatment and the futility of most of the efforts with urinary antiseptics which preceded it. Now, however, another specific and highly effective remedy has appeared in sulphanilamide. It is known that this drug acts on certain other bacteria besides the haemolytic streptococcus, and the original prontosil has in fact been successfully used more or less empirically for urinary infections for some time past. The first adequate and controlled study of which we are aware of the action of sulphanilamide in urinary infections is now reported by Dr. Meave Kenny[1] and his associates at the British Post-graduate Medical School, and their principal finding is that *Bact. coli* infections can regularly be cured within a few days: this series is composed of forty-six cases, including sixteen of pyelitis or pregnancy, and among them there was not a single failure. On the other hand, infections by other coliform bacilli and by cocci were found in a smaller number of cases to be more resistant. An interesting feature of this work is the comparison of clinical effect with the *in vitro* behaviour of bacteria causing the infections in urine containing the drug. Although sterilization was invariably secured *in vivo*, it did not always result *in vitro*, which is very much the reverse of usual experience with anti-

[1] *J. Lab. clin. Med.*, 1937, 22, 912.
[2] *Physical Aspects of Radium and Radon Therapy*. By Authority: L. F. Johnston, Commonwealth Government Printer, Canberra.

[1] *Lancet*, 1937, 2, 119.

septic action. As the authors point out, the drug presumably acts in the tissues as well as in the urine itself, and the *in vitro* test is therefore not a complete replica of its action in the body. Nevertheless, there appears to be another possible explanation of this discrepancy. The authors state that the action of sulphanilamide in urine is effective "over a fairly wide range of *p*H values, 5.2 to 6.8," although evidence or authority for this statement is not given, and they adjusted urine for *in vitro* tests to *p*H 6, which is the average for normal urine. On the other hand, Helmholz and Osterberg[2] state categorically that sulphanilamide is much more bactericidal in alkaline urine. Full details are not given and their work on the subject is evidently still in progress, but they secured "a great increase in bactericidal power" in a urine containing sulphanilamide by altering the *p*H from 6 to 7.5; a urine containing much excreted sulphanilamide and of *p*H 6 was also found to have less bactericidal power than a urine of *p*H over 7 but containing considerably less of the drug. In the light of these facts it seems likely that the failure of bactericidal action in some of Kenny's *in vitro* tests was due to the urine having been made too acid for optimum bactericidal action. It would be interesting to know whether the urine during sulphanilamide treatment actually becomes more alkaline, as Helmholz and Osterberg suggest; if not, it could easily be rendered so, and the advantage, which they point out, of being able effectively to treat proteus infections, in which the urine often remains persistently alkaline, is very great. These authors also claim to have shown that the conjugated sulphanilamide in the urine rather than the free is the active bactericidal agent. The whole of this subject calls for further detailed study, but it is already clear that here is another valuable weapon for the treatment of infections which used sometimes to be resistant to all efforts to eradicate them. According to Kenny its advantages are not only the rapidity and certainty of its effect but ease of toleration and comparative cheapness.

PROFESSOR ADOLF MEYER

Many of Professor Meyer's pupils met last April at the Henry Phipps Psychiatric Clinic, Johns Hopkins Hospital, Baltimore, to honour him on his seventieth birthday. This coincided with the beginning of his twenty-fifth year as director of the clinic. The first session was celebrated by the presentation of papers by eight of his many one-time students who are now working in most of the English-speaking countries and also in France, Switzerland, Norway, China, and Japan. Several of these papers were printed in a special number of the *Archives of Neurology and Psychiatry* (April, 1937) dedicated to Professor Meyer. The breadth of Meyer's interest in the personal, the social, the physical, and the constitutional facts presented by his patients—or, to use his words, his interest in "the psychobiologically integrated individual"—is adequately reflected in the varied topics discussed. These range from a neurolopathological discussion of syphilitic arachnoiditis of the optic chiasm; a neurosurgical report of the removal of a colloid cyst from the third ventricle; physiological studies of the cerebral circulation and conditioned reflexes; psychopathological reports on amnesia, metaphor, aversion, negativism, and the pathogenesis of hallucinations and delusions; clinical psychiatric studies of children presenting decreasing intelligence quotients; to articles dealing with special aspects of psychotherapy and prognosis. Meyer's career has shown the gradual unfolding of his unique abilities in formulation, teaching, and stimulation which have had a profound effect on the development of modern psychiatry. Meyer left Switzerland for the United States forty-five years ago, and worked in Illinois, at the Worcester State Hospital, Massachusetts, in New York—developing as part of the State Service what has become the New York Psychiatric Institute—and since 1910 he has been associated with Johns Hopkins Hospital. It is hoped that his collected writings will soon be published, so that they may reach a wider medical public.

MEDICINE IN THE MODERN WORLD

The medical profession has many public critics, and some of its most widely read detractors are in fact of its own household. No better antidote to calumny can be imagined than the recent collection of addresses by Lord Horder.[1] He covers a very wide range: he shows the firmness of his historical foundation in "The Hunterian Tradition"; his sense of the current needs of the time in "National Physique," "Old Diseases and New," and "Towards National Health"; and manifests his comprehension of the part which his profession ought to play in the modern world in his studies of the doctor as a humanist, as a contributor to the public happiness, and as a member of society. There is here no panegyric of the excellence of medicine and the medical man. This is a book by a physician at the head of his profession, and the man or woman who reads these essays, which persuade of their essential truthfulness by their quiet sanity, must feel that if they represent the mind of a leader and his opinions about medical men the profession must indeed be sound at heart. Lord Horder's work shows also his gifts as a writer and thinker. He has a way of expressing truths in clear images which strike home to the ordinary feelings of plain people. Lord Horder indeed may say, "*Nihil humanum a me alienum puto.*" He has spoken and written about medical subjects, but there is nothing here that the layman cannot understand, that is not a part of real human life. He sets his brother doctors an example which, if all followed, would greatly enlarge and strengthen its corporate spirit: that of general culture side by side with professional erudition.

[1] *Health and a Day.* By Lord Horder of Ashford. J. M. Dent and Sons, Ltd. (7s. 6d.)

On the occasion of the annual Buckston Browne Dinner on November 11, it is proposed to hold an exhibition of works of art by Fellows and Members of the Royal College of Surgeons of England, which will remain open for about three weeks and will be held in one of the Museum Rooms at the College. Any Fellow or Member wishing to exhibit some of his work, either pictorial or sculptural, is asked to communicate with Dr. John Beattie, Royal College of Surgeons, Lincoln's Inn Fields, W.C.2, as soon as possible.

ANAESTHESIA IN GENERAL PRACTICE

This is one of a series of articles, contributed by invitation

GENERAL ANAESTHESIA IN DENTISTRY

BY

W. S. McCONNELL, M.B., B.S.

The dental surgeon who calls in the services of an anaesthetist requires an anaesthetic which, though brief, must be tranquil, and must ensure that the patient feels nothing of the extraction and is able to walk home afterwards. He needs also the co-operation of the anaesthetist in supporting the head, using a gag, and maintaining an efficient throat pack. I propose to deal with the administration of anaesthetics to children and adults, both in the surgery and in the nursing home or private house, discussing the various factors which modify the choice of the method used and the manner in which the anaesthetist may assist the dental surgeon. The views expressed in this article are my own, and I have confined myself to a description of those methods which I constantly employ.

In recent years there has been a tendency to employ complicated nitrous-oxide-and-oxygen machines when simpler equipment would serve equally well. Unless the anaesthetist can give a satisfactory nitrous-oxide-and-air anaesthetic, using only a nose-piece, tubes, bag, and cylinders, it is unlikely that he will obtain the best results from a complicated machine, and, what is more, he may blame the apparatus for his failure. In private practice I use the simplest type of apparatus: cylinders of nitrous oxide and oxygen controlled by foot-keys, a rubber double bag, a small mixing chamber connected to the nose-piece, and a mouth inhaler.

Anaesthesia for Children

For the small child of 3 or 4 years of age ethyl chloride given on an open mask is satisfactory, because with nitrous oxide only a narrow margin divides too light an anaesthesia with associated cries and voluntary movements from partial asphyxia with cyanosis and jactitation. If the child is nervous it may be impossible to use nasal nitrous oxide, for the nose-piece will not be tolerated sufficiently close to the face, or the child may breathe exclusively through the mouth. A full face mask will overcome the difficulty, but will certainly scare the child and will produce but a brief period of anaesthesia. In such a case ethyl chloride may be given on the corner of the upturned bib, and should the child move the head there is no difficulty in following such movements with the napkin. It is important not to allow the intensely cold towel or bib to press on the child's face; two tubes of ethyl chloride should be available, as one may be knocked from the hand and broken.

Whatever method is chosen much tact and gentle handling will be necessary. My rule is to try persuasion for ten minutes: if this fails the parent is asked to decide whether force shall be used or less drastic measures, such as the production of sleep by drugs in bed at home. When told beforehand that he is to have a tooth extracted, and that he will be given something to breathe to take any pain away, even a nervous child will follow simple instructions. Much depends on the impression given to the child by the first anaesthetic in the dental surgery; there should be no question of creeping up and taking him by surprise. Every step of the procedure should be explained before the administration in fairness to the child and to the dental surgeon, for if any deception is practised he may lose the confidence of his small patient. In hospital practice it is not uncommon to remove eight temporary teeth in a small child at one sitting. Much depends on the skill of the anaesthetist as to whether the patient can be kept sufficiently quiet and still for such an extraction, using nitrous oxide and air or oxygen. If there is any doubt ethyl chloride should be employed.

Necessary Preliminaries

The child should be made comfortable in the chair, with the occiput well supported by the head-rest, helped by cushions if necessary in the case of very small children. If the legs are dangling uncomfortably over the edge of the chair and the child appears likely to slide off he should be made to sit tailor-wise with the legs crossed on the seat. The position of the teeth to be extracted should be noted, and also whether a Mason's gag will be required to change to the other side of the mouth. An attempt should be made to insert a dental prop before the induction of anaesthesia. Explain to the child that all good children go to sleep with their mouths closed, but that on this one occasion it is necessary to have it open; should persuasion fail the anaesthetic is started, but it is important not to allow the child to become completely anaesthetized before a Mason's gag is inserted.

In children deeply anaesthetized with the mouth closed the tongue may cause some respiratory obstruction, and spasm of the muscles of the jaw will result. Attempts to force the mouth open are more than likely to damage or displace a deciduous tooth, but by resting a gag in the mouth in the early stages of the induction it is possible to open the mouth gently as the anaesthetic proceeds. If the anaesthetic has been carried too far for the child to open its mouth voluntarily the dental surgeon should place a hand firmly on the child's forehead while the anaesthetist depresses the chin with one hand, inserting the gag into the already opened mouth and not using it to force the jaw open.

Respiration

The one safe guide to the progress of anaesthesia with ethyl chloride is the respiration. It is important to hear or see every breath from the moment of induction, and if from any cause the respiratory movements cease the drug should be withheld. In the early stages of induction the child may hold its breath; at such times the spray of ethyl chloride is stopped, the mask, however, remaining in position. When respiration begins once more further quantities of ethyl chloride are given until the breathing becomes automatic. If ethyl chloride is administered only in the presence of regular respiration possible causes of anxiety may be avoided. It should be apparent if respiration ceases that the cause is breath-holding during the induction, obstruction due to the tongue, spasm of the glottis at a later stage, or, finally, gross overdosage.

Spontaneous movements of the child's limbs are disregarded, and no reliance is placed on the presence or absence of stertor, the size of the pupils, or the direction of the squint. How much deeper the anaesthesia is carried after automatic breathing is established depends upon the amount of work to be done, but in no case should it be pushed until there is a snatch in the respiration, or until the breathing becomes shallow. No obstruction of the airway can be tolerated during ethyl-chloride anaesthesia, and in most cases the jaw must be held forward by a very definite effort on the part of the anaesthetist, particularly when lower molar teeth are being extracted and the fingers of the dental surgeon tend to depress the tongue.

During induction with a gentle stream of nitrous oxide blown from a distance of an inch or so from the nose the attention of the child may be distracted by a suitable story. This should be continued during the moments of awakening, and few children detect any loss of continuity. Most children can be persuaded to breathe through the nose: if not, then a mouth-piece through which nitrous oxide is blown should be employed in preference to covering the mouth with a hand, for it is not difficult to asphyxiate a child by such obstruction to the respiration.

A moistened marine sponge to which a length of tape has been securely fastened is always inserted as a throat pack before any extraction, as deciduous teeth readily slip out of the forceps. It is placed so as not to carry the tongue back but to form a diaphragm at the entrance to the fauces. If pushed too far back it may cause the patient to retch and displace the dental prop. If with nitrous oxide and air the procedure threatens to be prolonged added oxygen makes for a smoother and more tranquil anaesthesia, but with the disadvantage of possible nausea afterwards. No attempt is made to work with a definite percentage of nitrous oxide and oxygen, the mixture being varied to meet the requirements of the patient.

Anaesthesia for Adults

The patient should sit upright in the chair, with the head-rest supporting the neck and occiput. Saliva collecting in the mouth during the induction is then less likely to trickle to the back of the throat and cause coughing or retching, and the tongue, even if depressed by the fingers of the dental surgeon, is less likely to obstruct respiration. The legs should rest naturally and not be wedged against the foot-rest. The anaesthetist should be shown the teeth to be extracted, and should note the presence or absence of such fragile appliances as gold bridges or porcelain crowns, so that he may avoid resting a Mason's gag on them. A mouth prop is inserted by the dental surgeon. Induction is slow, and the metal nose-piece is held at a distance while nitrous oxide is allowed to stream towards the nose. The valve on the nose-piece should not be closed during the induction, as the expiratory difficulty so produced may cause the patient to breathe through the mouth. In cases of partial nasal obstruction or persistent mouth breathing a mouth-piece becomes essential, but the insertion of the throat pack may restore nasal breathing. The guide to anaesthesia is the change to automatic respiration. The dental surgeon is invited to begin the extractions, not by the spoken word, but by a sign or gesture. Many patients describe how they have heard an anaesthetist say "Right you are" or "She's ready now."

Assisting the dental surgeon during the extractions consists very largely in keeping out of his way. When a right lower molar tooth is being removed the left arm of the dentist, who will be standing behind the patient, should be allowed to encircle the patient's head; during the extraction of upper central and lateral teeth the nose-piece should be temporarily raised, and while upper molars are being removed the head should be held as still as possible and a finger employed to retract the lower lip and protect it from the pressure of the forceps. A Mason's gag should be inserted by sight, the blades resting on molar teeth and two fingers of the opposite hand clearing the lips as the closed gag is placed between them. The instrument is locked in the open position and held against the cheek by the pressure of an open hand, so that it will follow all the movements of the patient's head. If gripped rigidly by the handles it will rock on the teeth if the head is moved, with possible damage to fillings and inlays. At the end of the extractions the prop and mouth-pack are allowed to remain in position until recovery of consciousness is complete.

Difficult Cases

Two classes of male adults present some difficulty—namely, the alcoholic who fights and struggles when partially anaesthetized with nitrous oxide and the man who struggles before anaesthesia is complete and tears the nose-piece off while he is still conscious. If the extractions are few in number and unlikely to present any difficulty it may be possible to maintain anaesthesia in the first group with nitrous oxide and added air or oxygen. A mouth-piece may be essential, as such patients when struggling breathe very deeply and may change over to mouth breathing without warning. For the second type the only hope is a quick induction, but at the best this will be uncomfortable.

For such cases I have found satisfactory a small dose of evipan given in the upright position in the dental chair and followed by nasal gas. This method should not be used unless the patient has a friend who can take him home after resting under supervision in the surgery for a period of up to one hour afterwards. Evipan is not employed as a substitute for nitrous oxide or just because the patient "hates gas." It is suitable for the difficult patient with easy teeth, or the easy patient with difficult teeth, but not for the difficult patient with difficult teeth, as the dosage must of necessity be small.

Inquiry is made into the patient's past medical history, the pulse is counted for one minute to exclude irregularities, and the arms are inspected to find a suitable vein. A strap is placed round the pelvis of the patient and well down under the back of the dental chair, since there may be a tendency to slide down. A cushion on the arm-rest enables the forearm to remain comfortably in extension. A rubber tourniquet is applied, the skin cleaned with spirit, and the injection begun. The dental surgeon supports the head and jaw to ensure an airway and inserts a prop before consciousness is lost, maintaining it in position until anaesthesia is complete, since there is a likelihood of its falling out should the patient yawn. At the conclusion of the injection a pad should be placed over the site and the forearm flexed to avoid possible leakage of blood. If no dental prop is used to keep the mouth open during the induction much larger doses of evipan may be required, as some difficulty may be experienced in opening the patient's mouth.

The first sign of the onset of sleep may be seen when 2 c.cm. have been given; half a minute should be allowed to elapse before further quantities of the drug are injected. The object is to give the minimum amount of evipan to

produce a short period of anaesthesia. If too little is given the patient, when stimulated, may become quite uncontrollable; if more than sufficient is given the return to consciousness may be much delayed, and it may be some hours before the patient is fit to leave the surgery. With those addicted to alcohol, or in a highly nervous or apprehensive state, doses up to 5 or 6 c.cm. may be necessary.

The maintenance of an airway in a patient under evipan in the dental chair is particularly important. Obstruction such as is sometimes seen under nitrous oxide, when of necessity the dentist's fingers depress the tongue, cannot be tolerated. The amount of evipan given should never be enough to depress the respiration in any marked degree. Stimulation of the return of consciousness can be obtained by the inhalation of smelling salts or of carbon dioxide-oxygen mixtures.

Dental Operations in Nursing Homes

The induction of anaesthesia for dental operations in a nursing home, whether the patient is a child or adult, is similar to that for any major operation, and basal narcotics such as nembutal, avertin, and paraldehyde (which are described in another article in this series) may be used. To maintain anaesthesia ether vapour and oxygen or nitrous oxide and oxygen may be blown through a tube inserted through the nostril, leaving the mouth free for the dental surgeon. For the operation of removal of difficult wisdom teeth, in which the jaw is constantly depressed by the dentist, it is an advantage to employ an endotracheal tube, but for multiple extractions a short tube passed through one nostril into the oral pharynx will serve. A useful length for such a tube is the distance measured from the tip of the nose to the lobe of the patient's ear; the tube will not reach the vocal cords, and when employed it is necessary for the anaesthetist to support the mandible throughout the operation. If the patient's head is to be covered with towels care should be taken to see that the eyes are closed, as they may be injured by contact with such coverings in the movements of the head involved in a difficult extraction.

The progress of anaesthesia throughout the operation is estimated entirely by the respiration. The patient is maintained at a level of anaesthesia at which he does not cough when, from the manipulations of the dental surgeon's fingers on the throat pack, the posterior pharyngeal wall is irritated. At the conclusion of the operation the anaesthetic is discontinued and the throat pack removed. If the patient does not cough within a minute or so carbon dioxide and oxygen are blown through the nasal tube. On the return of the cough reflex the nasal or endotracheal tube is removed, but the mouth-prop is allowed to remain. If the prop is taken away too soon some patients tend to clench the teeth and allow the tongue to cause obstruction or grind the teeth, with the possible dislodgement of an inlay or filling. Once in bed the patient is turned well over to one or other side to ensure that any oozing from the sockets dribbles out of the mouth.

The following officers of the Women's Medical Service for India have received the Coronation Medal: Drs. H. M. Franklin, M. C. Murphy, E. Hamilton-Browne, H. M. Lazarus, Grace Stapleton, L. de Menezes, Ruth Young, G. Patel, N. Mucadam, Torrance-Allen, L. Ghosh, Roulston Mitton, K. McDermott, H. Keane, A. Dodhi, H. Acheson, D. Bolton, E. Wingate, U. Morton, I. Keess, N. Proctor-Sims, J. Orkney, C. L. Houlton.

"THE SURGEON'S LOG"

AN ANALYSIS OF THE HEALTH OF THE CREWS OF A LARGE FLEET OF MERCHANT SHIPS

BY

W. ARTHUR TATCHELL, M.R.C.S., L.R.C.P.

Medical Superintendent, Blue Funnel Line and Glen Line

There is no standardized "surgeon's log," each shipping company having its own form; nevertheless, though details may vary, the principal items recorded are the same. Our log is rather comprehensive, giving the name of the port where the ship is lying or to which it is bound, the numbers of the crew and passengers, the daily temperature, and a list of the sick, their treatment and progress. At the end of each voyage the log, with abstracts of cases and a list of accidents, however trivial, is either brought by the surgeon or forwarded to the medical superintendent at the head office of the company. There it is carefully examined by the medical superintendent and a summary of cases recorded. The log, when labelled and numbered, is placed in order with hundreds of others for future reference when necessary.

A Year's Statistics

These final statements, which I have made annually, are, I think, both enlightening and instructive, and it occurred to me that the publication of one year's statistics of the crews of a large merchant fleet would be of interest and possibly useful to those who are responsible for the health of seafaring men. To know what the principal diseases are from which seafaring men suffer and which cause them to be put off duty may help to guide those responsible for their health in an intelligent direction in the matter of prevention.

Health at sea, as on land, is largely ruled by conditions of living, food, and available treatment. The different standards for these set by owners will, I believe, be largely reflected in the entries in the surgeon's log. Climate must be taken into account. A North Atlantic company will probably have different results from one whose ships are trading for half their voyages within ten degrees of the equator. The fleet of the company concerned in the present analysis consists of eighty-five ships, varying in tonnage from 3,066 to 14,646 tons gross. The policy of the owners is to have a surgeon in each ship, although legally required to carry one in only fourteen of their ships.

The ships from which the statistics are taken sailed between the United Kingdom, and the Straits Settlements, China, Japan, the Dutch East Indies, and Australia. I have omitted for reasons of accuracy our Western Australia ships, which sail between Singapore and Fremantle, the transpacific service between Hong Kong and Vancouver, ships plying between New York and the Far East, and those flying the Dutch flag. The crews are composed of Europeans and Chinese; two ships were staffed entirely with Europeans. The Chinese are drawn principally from Hong Kong and Shanghai. All crews are carefully medically examined before signing on, the Chinese by the ship surgeon at the port of engagement. All are vaccinated at least once every three years, while the eyesight of each officer is tested once a year and a full medical examination made before each promotion. The food supplied is of good quality, well prepared, and not rationed.

The average time for the voyages was 119 days, and the average crew per ship was eighty-one, composed of forty-six Europeans and thirty-five Asiatics. In 1935 the total number of "men-days" at sea was 1,268,000, and the time lost through sickness and accident was only 4,786 days, giving the remarkably low percentage of 0.4. The average time lost per man was 1.26 days for Europeans and 0.69 day for Asiatics. This does not necessarily

include the days spent in hospital by the twenty-three Europeans and seventeen Asiatics who were landed abroad.

Chief Causes of Illness

The chief causes of illness were inflammatory and febrile conditions, especially influenza. There were only a few cases of malaria. The number of days on which Europeans were off duty from all febrile causes was 633, being 18.9 per cent. of the total days lost by Europeans from all causes—that is, 3,356. For Asiatics the figure was ninety-nine days, a percentage of the total of 1,430 days lost at sea of 6.9. Asiatics were less susceptible to influenza, only forty-six days being lost by them from this cause, or 3.2 per cent., whereas the corresponding figures for Europeans were 433, or 12.6 per cent. The same observation could be made with regard to "colds and coughs." It might be presumed that the Asiatics working in the hot engine room and stokehold and experiencing the great contrasts in temperature when they came on deck would suffer more than those whose work was on deck alone. But it appears that mere change of temperature, apart from other factors, is not prejudicial.

Injuries are classified under the headings of "fractures," "contusions," "wounds," and "burns and scalds," and the number of days off duty on board ship from all four injuries was 660 for Europeans, or 19.7 per cent., and 319, or 22.3 per cent., for Asiatics. Rheumatism and inflammation of joints seem to affect the Asiatics more than the Europeans. Neuralgia deserves mention with rheumatism, as *both* occur chiefly on encountering warm to hot weather. This is also the opinion of other observers.

Tropical diseases on board ship are very rare. Only six cases of malaria occurred among the 2,690 Europeans and three among the 2,065 Asiatics. There were seventeen cases of diarrhoea among Europeans and two among Asiatics; one European and one Asiatic had typhoid, and two Europeans had dysentery and enteritis (cholera). These were the only diseases of a tropical nature which were recorded, though it is possible that a few cases of coastal fever may have been classified with influenza as being clinically indistinguishable therefrom. The percentage loss of time from tropical diseases was 3.2 for Europeans and 2.5 for Asiatics.

The commonest types of skin diseases are those caused by various microsporons. Prickly heat rashes are confined almost entirely to the Tropics, and generally yield quickly to treatment with the use of fresh and the avoidance of salt water. Boils and pustular rashes are occasionally met with. Pediculosis is rare, there being adequate facilities on board the ships in the way of baths and washhouses for clothes to ensure personal cleanliness. Other types of skin troubles are so infrequent as to be represented by isolated cases. It may be noted that cuts, abrasions, ulcers, burns, and scalds, also most of the other skin affections, heal more slowly in the Tropics than in temperate climates. This may be attributable to the almost constant moist state of the skin rendering it impossible to keep lesions dry, and affording a more suitable medium for the growth of germs.

Effects of the Sun

There were eighteen cases of sun and heat strokes among Europeans and three among Asiatics. One must discriminate between the cases attributed to the direct rays of the sun and those due to heat. I think the vast majority of cases were, and are, due to heat. Real sunstroke is reputed to occur at two periods of the day—namely, the rising and setting of the sun, whether the atmosphere be clear or dull, and the "stroke" is caused through either the eyes or the back of the neck. I have not come across a case at sea, but the two authentic cases I saw in China happened during the setting of the sun on dull days at an altitude of 3,500 feet. Heat stroke can occur at any period of the day, but seldom in the early morning or evening. I may add that our officers have derived great benefit, including freedom from fatigue and headache, from wearing neutral-tinted glasses on the bridge and while working on deck during both bright and dull days. Racial susceptibility to disease is not well marked on board ship in our experience of the voyages considered. Pulmonary tuberculosis was rare, but a few cases were reported among the Chinese. Cases of beriberi, which is common in South China, were extremely rare. The latter are difficult to diagnose if the disease is in its early stages when the patient is examined, but any sufferer is soon restored to health with the good food supplies of meat, fish, eggs, and vegetables.

As to the morale of the crews, both the Asiatics and Europeans are a steady class of men. The amount of time lost through vicious propensities is negligible. Those members of the medical profession or general public who regard the seafarer as a hard-drinking morally lax person are entirely in error. At sea deck games are encouraged, and when in port football and cricket matches are frequently arranged; also other recreational facilities are provided in the company's clubs at various ports.

Conclusions

The different diseases, etc., recorded here are those causing loss of time only. There were many others mentioned in the logs, but their effect in this respect was insignificant. Considering the statistics as a whole and that the average time lost per man during the year was one day only, the conclusion must be that the seafaring life is a comparatively safe and healthy one on the routes and under the conditions considered where medical aid is constantly present. Is this a fair sample of the vast majority of trading routes and the experience of other shipping companies?

I wish to express my thanks for the valuable assistance of Dr. J. A. Tobin and my secretary, Mr. A. B. Tytler, in preparing the statistics from which this material has been compiled.

VITAL STATISTICS OF MALTA

The vital statistics of the Maltese islands (Malta and Gozo) showed a remarkable improvement in several respects in 1936, though the Chief Government Medical Officer (Dr. A. V. Bernard) in his annual report emphasizes the fact that in vital statistics based on small populations considerable fluctuations may occur in short periods due to ephemeral and fortuitous causes. The islands have a population of 262,165, which is about ten times as great as it was 1,000 years ago. The birth rate is steady at 33.8 per 1,000, and has not differed markedly during the last ten years; it stands where the birth rate for England and Wales stood fifty years ago, and where the birth rate for British India stands at present. The death rate for 1936 (17.61) shows a considerable drop, and compares with an average of 22.3 for the last nine years. The infant mortality, though still at the very high figure of 190 per 1,000 births, also registers a big fall from the average of the previous nine years of 280. The mortality of children under 5 has declined to 66 per 1,000 from rates which during the last ten years have approximated to 100. The high infant mortality accompanies a very high birth rate, and the population of Malta is steadily increasing at a more rapid rate than in countries where a low infant mortality is coupled with a diminishing birth rate. Of the notifiable diseases the commonest is undulant fever, of which there were 873 cases in 1936 (the lowest figure since 1927) and fifty-two deaths. The decrease in the incidence of this disease must be ascribed either to a diminution in the diffusibility and virulence of the infecting agent or to an increased resistance to the disease among a larger proportion of the population due to immunity derived from high prevalence. An undulant fever research station has been at work since the beginning of last year, and progress is also being made in the scheme for setting up a milk pasteurization plant.

Nova et Vetera

JOHN SNOW (1813-58)

A PAINSTAKING STATISTICIAN

Although Charles Creighton was a great historian his judgements of the significance of scientific achievements have seldom been confirmed by posterity. His heroes, Pariset and Robert Watt, live only in his pages; the fame of even Pettenkofer, whom he admired, is dim. Edward Jenner, on the other hand, to whom he attributed so many evil and so few good qualities, and Robert Koch, at whom he jeered, are not likely to be forgotten. Two epidemiologists Creighton despised were William Budd and John Snow. To Budd he devoted only a depreciatory footnote, but Budd's "fallacies or paradoxes" have been reprinted and his life written. John Snow had even shorter shrift. After describing the epidemiological drama of Golden Square, Creighton wrote:

"The whole incident was seized upon and worked up by Dr. Snow, who had written a speculative essay in 1849 upon the probability of cholera being conveyed by water, according to the similar theory of Parkin in 1832. The Board of Health, having very full data before them of the Soho outbreak in all its aspects (including a whole biological treatise upon the organisms found in water), did not adopt Snow's conclusion, although he had enthusiastic followers at the time, and has probably more now." (*Hist. of Epidem. in Britain*, 2, 854.)

At least Creighton's concluding words are true. The Commonwealth Fund has just reprinted Snow's chief epidemiological papers with Richardson's memoir of him and an enthusiastic introduction by Professor Wade Frost of the Johns Hopkins School of Hygiene.[1]

Snow on Cholera

Whether, having before him the fully documented second edition of Snow's pamphlet (published in 1855), Creighton's sneer at the essay of 1849 were worthy of a historian of his rank may be doubted. But we must not run into the opposite error of sneering at Creighton merely because Snow's "speculations" regarding cholera have proved in the long run much more illuminating than Creighton's own conclusions. It is true that some of Snow's opinions *were* only speculations. He thought that epidemiologically plague, malaria, and yellow fever were *in pari materia* with cholera, and his address "On Continuous Molecular Changes" (also reprinted) might well have seemed to so erudite a man as Creighton superficial. Snow's biopathology was not much in advance of Fracastor's, and not at all in advance of Henle's essay published thirteen years before Snow's. Snow's depreciation of ancient epidemiology does not attest any serious knowledge of the subject. These are, we think, palliations of Creighton's conduct; but only palliations, for his account of Snow's work *is* misleading, and it is well that justice has been done to the memory of an epidemiologist whose strong points and weak points were characteristically English.

Born in 1813 and bred a general practitioner, Snow settled in London, and his contact with medical science was mainly through the Westminster Medical Society (later to become the Medical Society). After 1846 he specialized in anaesthesia, and devoted much of his leisure to the physiology of that subject; he was at work on a treatise on chloroform and other anaesthetics in the year of his death, 1858.

Snow's epidemiology was a labour of love. Professor Frost speaks of him as "endowed with the ability to think in straight lines, and the courage to follow his thought." That is, we think, a well-deserved eulogy. If the devil's advocate retorted that Snow was a man of one idea who did not give much attention to other ideas, that would also be true. But, and this is Snow's supreme merit, he was almost Darwinian in the trouble he took to assemble not some but all of the relevant statistical facts. His hypothesis was that cholera had its biological origin in a vital something which passed into the dejecta of patients. He did *not* suppose that all cases arose from the drinking of contaminated water, but he did suppose that water was the chief vehicle of infection. Therefore he set himself to study the local distribution of cholera in a city having various sources of water supply.

"I felt that the circumstances of the cholera-poison passing down the sewers into a great river, and being distributed through miles of pipes, and yet producing its specific effects, was a fact of so startling a nature, and of so vast importance to the community, that it could not be too rigidly examined or established on too firm a basis."

The Southwark and Vauxhall Water Supplies

Snow's statistical and field investigation was thorough. The case of the Broad Street Pump has such an element of melodrama, and has so recently been summarized by Dr. Harold Scott in his excellent book *Some Notable Epidemics*, that most people think only of it. But, as a piece of field and statistical investigation, we should give even higher praise to the tracing out of households taking the water of the Southwark and Vauxhall Company in 1854 and the statistical presentation of results. Of course Snow did not prove that the customers of the Southwark and Vauxhall Company were actually poisoned by the company's water, but he did show that in the first seven weeks of the epidemic they died of cholera at from eight to nine times the rate sustained by the customers of the Lambeth Company. Further, he made a special investigation of that part of the area in which both companies operated.

"The inquiry was necessarily attended with a good deal of trouble. There were very few instances in which I could at once get the information I required. Even when the water rates are paid by the residents they can seldom remember the name of the water company till they have looked for the receipt."

In the end he concluded that in 286 of the fatal cases the house where the victim fell sick was supplied by the Southwark and Vauxhall Company and in only fourteen by the Lambeth Company. In the other cases the sources were varied. As, according to a parliamentary return the Southwark and Vauxhall Company supplied 40,046 houses, the Lambeth Company 26,107, the disproportion in incidence was enormous. It is true that Snow was not able to ascertain the total distribution by houses in the particular part of the area served by both companies, the figures just quoted are for all areas, so that he did not prove statistically that in houses in the same street the customers of the Southwark and Vauxhall Company were taken and those of the Lambeth Company spared; had he done so the case would have been logically complete, for the factor of elevation—stressed by Farr—would have been neutralized; but that would have been an impossible task for a private investigator. Farr, unlike Creighton, did not sneer at Snow's work; on the contrary, he made special reference to it (in the Seventeenth Annual Report of the Registrar-General), and in his own statistical researches, particularly in his terrible indictment of the East London Company (contained in the report on the epidemic of 1866), twelve years later, virtually adopted and extended Snow's method of statistical investigation. Although without scientific precision, the following remark has some historical interest.

"Many of the people receiving this latter supply [that of the Southwark and Vauxhall Company] were in the habit of tying a piece of linen or some other fabric over the tap

[1] *Snow on Cholera. Being a Reprint of Two Papers by John Snow, M.D., together with a Biographical Memoir, by B. W. Richardson, M.D., and an introduction by Wade Hampton Frost, M.D.* London: H. Milford, Oxford University Press. (10s. 6d.)

by which the water entered the butt or cistern, and in two hours, as the water came in, about a tablespoon of dirt was collected, all in motion with a variety of water insects, while the strained water was far from being clear."

Such was the water supply of part of the metropolis as recently as 1854.

Snow's range was narrower than Budd's, who had the advantages of a wider education and a longer life, but there is much similarity between the work of the two. Snow was a better statistician than Budd and before him in setting the investigation of cholera upon a fruitful line of study; Budd had better opportunities—perhaps a greater flair for field investigations in country districts. Both influenced for good official research and public health administration. It is fitting that the principal writings of both should have been reprinted in the same series.

M. G.

RECREATION AND PHYSICAL FITNESS

BOARD OF EDUCATION HANDBOOKS

H.M. Stationery Office publishes this week two handbooks of recreation and physical fitness; one dealing with youths and men and the other with girls and women. They are profusely illustrated and may be obtained from the Stationery Office or through any publisher, price 2s. 6d. Sir Arthur MacNalty contributes a foreword to each volume.

The New Policy of Physical Education

The handbooks, which have been prepared by the Board of Education, were foreshadowed in the Board's Circular 1445, which was issued early in 1936 and outlined a new policy on physical education for which the lead was given by the British Medical Association when it appointed its special committee in January, 1935. That policy emphasized the importance of better facilities in the schools in the form of gymnasiums, changing rooms, shower baths, playgrounds and playing fields; of more time for physical training and games in the curriculum; of a full supply of teachers trained in modern educational gymnastics; and of the appointment by all local education authorities of organizers of physical education.

The circular has been supplemented and followed up by the Government's scheme for encouraging recreation and physical fitness among those who have left school. The scheme was explained last February in a White Paper (Cmd. 5364) and has now been implemented by the new Physical Training and Recreation Act. A National Advisory Council has been called into being, together with a central Grants Committee. Local area committees are in process of formation over the whole country. A National Physical Training College for leaders is to be established.

Physical Training Organizers

The organizers employed by local education authorities, who are regarded by the Board of Education as the keystone of physical education in the areas where they have been appointed, have already done much not only to improve the standard of physical education in the schools but also to stimulate the enthusiasm of those who have left school. They have induced their authorities to help and they have often been able to advise the various voluntary bodies engaged in recreational work. "Keep-fit" classes are spreading all over the country; the area of playing fields open to the public is growing; open-air swimming baths are immensely popular; and camping and hiking are becoming national pastimes. There is thus to-day both a spontaneous and an official movement towards physical fitness and recreational activities for all.

The two handbooks therefore come at an opportune moment, for their main purpose is to give advice and guidance to all those who are responsible for conducting the activities of youth organizations, clubs, classes, and centres, and for selecting and training leaders.

Guidance for Youths and Men

In the book for youths and men a chapter deals fully with gymnastics in its broadest sense and includes three groupings of exercises: free-standing and floor exercises with a "bite" in them; stronger exercises, some of them with apparatus; and jumping, vaulting, and agility exercises. In combination these groups form a well-balanced treatment. Such a combination is commonly known as a gymnastic table, and a number of tables are given for the use of leaders. Exercises which should be performed with a rhythmic swing have not been overlooked, and there is also a comprehensive list of the various gymnastic exercises. Physical exercises and gymnastics are included in the handbook because these forms of activity give alertness, agility, control, balance, poise, and rhythm.

The teaching and organization of team ball games, national team games, general athletics, swimming, dancing, boxing, skipping, and wrestling are also fully dealt with, and a chapter on camping reflects the popularity of camping holidays. In the appendices there is advice for the organization of athletic sports, swimming sports, and boxing meetings.

Girls and Women

The book for girls and women is arranged under three main headings: general introduction; schemes of indoor training; schemes of outdoor training. A wide range of activities has been included, all of them within the scope of the working girl or woman who wants exercise but has limited opportunities for enjoying it. Differing ages, interests, and physical abilities are all taken into account. There is "keep-fit" work for those who like to take their "daily dozen" in company, and gymnastics for the more energetically inclined. To women and girls who prefer a more aesthetic and musical approach the section on dancing will appeal. A comprehensive survey is made of all the main open-air activities. Hockey, net-ball, cricket, tennis, rounders, stool ball, and lesser team games are dealt with in more or less detail, while swimming, athletics, and camping have chapters to themselves. In this book, as in the companion book for youths and men, the beginner player and the amateur leader as well as the professional coach have been kept in mind.

The International Spa Congress will take place in Budapest, under the presidency of the Archduke Joseph Francis, from October 7 to 14, in association with the inaugural meeting of the Royal Hungarian Academy of Science. A wreath will be placed at the foot of the statue of Semmelweiss, and visits will be paid to the more important thermal establishments in the vicinity. Five sub-committees have been constituted to organize the various scientific lectures and discussions, which will relate to the medical, technical, economic, legal, and propaganda aspects of spa treatment. Special arrangements are being made to exhibit to delegates and visitors the cultural, ethnographical, and tourist characteristics of Hungary. Included in the large and diverse programme of topics for consideration are the importance of thermal baths as regards public hygiene, medical and staffing questions relating to thermal establishments and spas, dietetics, and statistical work at spas. Lectures will be delivered in English, French, German, Italian, and Hungarian. A medical postgraduate course will be held concurrently, and the centenary of the Royal Medical Society of Budapest will be celebrated during the week of the Congress. Further details may be obtained from the Congress Office, Dorottya Utca 11, Budapest V, Hungary.

Local News

ENGLAND AND WALES

Epsom College Pensions

Later on in the year the Council of Epsom College will award two "France" pensions of £30 per annum each to duly qualified medical men in reduced circumstances. Candidates must be not less than 55 years of age, and, if single, must not be in receipt of an income, independently of any allowance from the College or the Royal Medical Benevolent Fund, of more than £100 per annum. If married, the combined incomes of the candidate and his wife must not exceed £150 per annum. Forms of application may be obtained from the Secretary, Epsom College Office, 49, Bedford Square, London, W.C.1.

Child Welfare in Wales

Speaking at the opening of a new maternity and child welfare centre at Glyn Neath during his official visit to South Wales last week, Sir Kingsley Wood said a child population, healthy and sound, was more than ever important to-day, not only for the sake of the children but because the fall in the birth rate had reduced the proportion of young lives in our population while the fall in the general death rate had increased the proportion of the older people. Infant mortality in England and Wales remained at a low level, and during the last ten years the rate of mortality had been less than half what it was at the beginning of the century. This had been largely due to the efforts of the State and the local authorities and voluntary agencies by the improvement in the environment of the child. Social, domestic, and sanitary and better housing conditions had played a great part. While the arrangements for supervising the health of children under the age of 18 months or 2 years were generally satisfactory, he desired to see a more systematic and periodical health visiting of all children under 5 who did not attend school. The further establishment in certain areas of special "toddlers clinics" and of day nurseries was also well worth while. Local authorities had in the main spared no trouble in making provision for destitute children in suitable homes, but perhaps the most important thing to-day was to find the right people to look after the children. Buildings were important but far less so than the staff. Children should not be retained in institutions but in homes under the guidance of people who studied their needs and made them useful citizens. In Wales there had been a continued and considerable expansion of services. In 1926 there were thirteen ante-natal clinics at which about 10 per cent. of expectant mothers attended; to-day there were 104 such clinics, and about 40 per cent. of the mothers attended them. In 1926 there were 250 infant welfare centres and there were over 300 to-day, and nearly 70 per cent. of the children under 5 attended them. He was glad to see that the Commissioner had been able to give, or had undertaken to give, grants towards the erection of twenty-four maternity and child welfare centres.

In an address later in the week to the representatives of the Welsh local authorities at Cardiff, the Minister said he hoped early in the new Session to introduce in the House of Commons two important measures, one to reduce the age limit for the award of pensions to the blind and the other to provide medical care for young persons who had left school.

There was still a considerable housing programme to be undertaken, at least 300,000 new houses being required to complete the slum clearance and overcrowding programme within the present statutory standard. New financial housing provision would have to be determined by Parliament early next year. In co-operation with the industry he hoped to make proposals for securing a reduction in the price of liquid milk to local authorities for the purpose of their maternity and child welfare arrangements. Local authorities would be in a position to extend their present schemes, under which milk was made available either free or at a reduced price, as circumstances might require. The expenditure of local authorities in South Wales on milk and food had more than trebled in the last ten years, and he hoped this policy of extension would be continued. There had been two important achievements in Wales during the past year: both the infant mortality rate and the tuberculosis death rate were the lowest so far recorded in Wales. But while this was gratifying, there were many conditions in the country that called for further treatment and attention.

Light for the Blind

In 1903 Miss Winifred Holt (now Mrs. Mather) and her sister became interested in the welfare of the blind, and founded an association, which three years later became the New York Association for the Blind, to prevent unnecessary blindness and to enable the blind to help themselves. The association flourished exceedingly, and on August 13 Mr. and Mrs. Rufus Mather told an interesting story of the work done by what has now become an international organization. The meeting was held by the kind permission of the Master and Wardens in the Clothworkers Hall, Mincing Lane. An account was first given in simple untechnical language of the association's projects, and two films were shown to demonstrate how an illiterate public could be taught to avoid preventable blindness. Short legends were appended to explain each scene, and these legends could be translated into the language of the country where they were being shown. Preventable blindness, it was explained, might be grouped under the headings of bad living conditions, dirt, insufficient nourishment, industrial accidents, improper lighting, trachoma, and ophthalmia neonatorum. Much had already been done in the United States, South America, and the West Indies. Mr. and Mrs. Mather had personally visited Norway, Denmark, Poland, Hungary, Egypt, Turkey, India, China, and Japan. In each country they had received help and encouragement from the heads of the administrative departments, and as the journeys had been made at their own cost the association had not been put to any expense.

SOUTH AFRICA

Pneumonia in Rand Miners

The report for 1936 of the health department of the Central Mining Rand Mines Group includes a survey of the incidence of pneumonia among the miners and the steps taken to combat this disease. In 1936 lobar and bronchopneumonia accounted for 4.46 per cent. of the total morbidity, and for 36.91 per cent. of the total mortality. Since the figures as far back as 1915 were 6.8 per cent. and 36.41 per cent. respectively, it appears that progress in dealing with this question has not been too satisfactory. During the first decade of the century the mortality from pneumonia alone was nearly twice the present mortality from all diseases, and to this factor may be partly attributed the prohibition of the recruitment of natives from north of latitude 22 degrees south. The practice of inoculation at first produced favourable results, but in recent years its protective value appears to have become negligible. It was suggested that this might be due to a change, clinical or bacteriological, in the type of pneumonia encountered. Careful investigation, however, disproved this theory. The report quotes a statement from the *American Journal of Public Health* (December, 1936) that "at the present time the chief reliance in the field of

prevention must be placed on isolation of the patients." Large-scale therapeutic trials were carried out with massive doses of vitamin A in the form of liver, liver extracts, or concentrated oil preparations. Although favourable results were at first obtained, a further and more extensive trial led to the conclusion that administration of vitamin A had no advantage over symptomatic treatment. Nor did the employment of sodium nucleinate, quinine, pneumococcal vaccine, serum, "omnadin," or "aurodetoxin" produce any significant results. The report summarizes the question by stating that intelligent symptomatic treatment and good nursing still constitute the best means of combating pneumonia as it affects natives employed in mines.

Correspondence

Expulsion of Placenta Praevia in Advance of Foetus

SIR,—Dr. J. W. Nankivell's graphic description, in your issue of September 11 (p. 527), of one of the most unusual happenings in midwifery practice must have interested all ardent obstetricians. The likelihood of such an occurrence is greatly lessened in these days by the improved modern methods of management of cases of unavoidable haemorrhage—even Caesarean section in certain instances of the complete placenta praevia. Things were very different in the last and preceding centuries, and the writers of those days make many references to cases in which the delivery of the after-birth preceded that of the child.

William Smellie himself describes cases and discusses their possibilities. Dr. Nankivell would, I am sure, enjoy reading Case 158 (McClintock's edition; vol. ii). Called by a midwife to a case of flooding, Smellie "found the placenta pushing through the external os [the term in his day for the vaginal orifice]; and the delivery of this was immediately followed by that of the child, which was alive, although the placenta came first. The midwife told me that when she found the placenta presenting, she was cautious of touching it with her fingers, remembering that when she attended my lectures I had observed that the death of the child, in flooding cases, might be owing to its losing blood from the laceration of the cake." Later he says, "but in such cases the child is commonly dead."

Amongst other writers Francis Mauriceau (in 1683) and Pierre Dionis (1729) describe these cases, and they both refer to "an old Practice amongst Midwives, to warm Wine in a Skellet, and put the after-birth into it before they separate it from the new-born Child; fancying that the Spirits of the Warm Wine are carry'd to the Child by the Navel String, and bring it (as they express it) to Life again. But tho' this is of no service to it, the Surgeon must by no means declare against it; for if the Child, having lost too much Blood, recovers not, the good Women will not fail to charge him with the murder of it."

This rare natural occurrence has even been advocated as a desirable method of treating certain cases of placenta praevia. Sir James Simpson, in 1841 and 1844, read papers before the Obstetric Society of Edinburgh to suggest and support this line of treatment. He considered it less dangerous, and one can see his point, than the practice then prevalent of forcibly extracting the child as quickly as possible after turning it, whatever the degree of dilatation of the cervix.

In Dr. Watt Black's *Selected Obstetrical Works* of Sir James Young Simpson (Edinburgh, 1871) there is given a "general tabular view of one hundred and forty-one cases in which expulsion or extraction of the Placenta preceded the birth of the child."

All's well that ends well, but I feel certain that Dr. Nankivell, and the family doctor who acted so promptly, would like to have had available for such a case a similar Maternity Emergency Service to that which Professor Farquhar Murray started in Newcastle-on-Tyne in 1935. Dr. Smellie would have given the opiate Dr. Nankivell prescribed, but how delighted he would have been to witness the improvement in the woman's condition brought about by the house-surgeon's intravenous saline and Dr. Facey's blood-transfusion.—I am, etc.,

Sheffield, Sept. 11. MILES H. PHILLIPS.

The "Other Half" of Medicine

SIR,—In your issue of August 28 Dr. Strauss saw fit to publish in full a letter written to another medical man about a patient. After some remarks Dr. Strauss states his belief that treatment given by him will result in a spontaneous remission of this patient's symptoms within six months.

Dr. Strauss's method of advocating the treatment he practises is not unfamiliar in connexion with forms of therapy employed outside the medical profession, but inside the profession, at least in the half to which I belong, it is still regarded as objectionable. May I venture to hope, Sir, that in future you will discourage the publication within your columns, by third parties, of reports from one medical man to another, whether for purposes of disparagement or otherwise.—I am, etc.,

London, W.1, Sept. 8. D. EVAN BEDFORD.

Sulphanilamide in the Treatment of Gonococcal Infections

SIR,—The necessity for a specific remedy in cases of gonococcal infection is so great as to be an international problem. Any research with this object in view is to be encouraged, particularly as gonococcal infection has long been a Cinderella among diseases from the aspect of investigation. It was therefore with considerable surprise that we read in your columns of September 11 the deprecatory account of the clinical value of sulphanilamide in gonococcal infections. The statement by Dr. Anwyl-Davies that sulphanilamide administered orally in acute cases of gonorrhoea is ineffective cannot be allowed to pass unchallenged.

During the last fourteen months we have had considerable interest in the action of *p*-aminophenylsulphonamide (prontosil album) in the treatment of gonococcal infections, and during this period it has been used in about 100 cases. Our early experiences showed that with an oral dosage as low as grains v t.i.d. occasional cases were seen showing rapid and marked improvement. With this dosage the number of cases responding were few but encouraging. Later, various schemes with a larger dosage were instituted, including the dosage utilized by Dees and Colston.

Recently we have given prontosil album orally in doses of grains xv t.i.d. for several weeks if necessary. Cases of acute gonococcal urethritis in the male have received this amount, some with no other treatment, some with daily irrigation with saline, and some with daily irrigation with pot. permang. 1 in 8,000. We have found that

the results in conjunction with daily urethral irrigation with pot. permang. are most encouraging, and were considerably better than when saline or no urethral irrigation was used. Of twenty-nine cases of acute gonococcal urethritis subjected to this dosage excellent results have speedily followed in twenty-one. Frequently the discharge has ceased and all symptoms have been relieved within three days. None of the twenty-one cases developed any complications. In other cases excellent results have been obtained in acute epididymitis and acute prostatitis. Favourable results have also been experienced in some cases of acute salpingitis and in vulvo-vaginitis.

Surely it will be a great calamity if the experience of Dr. Anwyl-Davies and his report to the Therapeutic Trials Committee of the Medical Research Council is allowed to stultify further research with a remedy which is of greater promise than any treatment that has been available in recent years.—We are, etc.,

D. ERSKINE.
A. G. JOHNSON.
V. E. LLOYD.

Guy's Hospital, S.E.1, Sept. 13.

Athletic Injuries of the Knee-joint

SIR,—After reading Mr. W. E. Tucker's excellent and very practical paper in your issue of September 11 (p. 525) one felt it a pity that he had not included in his otherwise very comprehensive article one or two further points which are of constant value to the general practitioner and yet not as widely recognized as they should be.

1. *Adhesive Strapping.*—While one is delighted to find Mr. Tucker stressing the importance of adequate fixation for a torn ligament or other joint structure, he omits to mention firm adhesive strapping, applied in successive layers in various directions so as to give support to the torn ligament while allowing activity in other directions. This is much more acceptable to the patient than plaster-of-Paris, which excludes him from his bath and has more weight and precludes most forms of sport. I have found adhesive strapping most valuable for all but complete tears, and even severe injuries yield to it. I had occasion to treat a man who tore most of the internal lateral ligament of his knee on the first day of a ski-ing holiday. After the knee was controlled by adhesive strapping in many layers he was able to continue his ski-ing for the rest of his three-weeks' holiday, provided he avoided Telemark turns on the injured leg, and he went all over rough snow and up and down mountains. After removal of the strapping some light adhesions were cleared up by cycling.

2. *Manipulation Without Anaesthesia.*—While agreeing heartily with Mr. Tucker that manipulation by force is resorted to far too often in these cases, I feel that he has not drawn sufficient attention to the frequency with which quite small local adhesions may keep up swelling and pain in a joint and not clear up with ordinary physiotherapy, yet yield dramatically to a forced movement judiciously applied while the patient is conscious but off his guard. In this method there is no danger of tearing any other structures or stretching muscles beyond their normal length. If the time and direction are judged correctly, which are matters of experience, the relief is immediate and the patient regains complete range of the joint or, in severe cases, steadily progressive increases of range.

3. *Graded Wedging of Shoes.*—The importance of taking strain off the knee-joint after injury by balancing the foot correctly cannot be exaggerated, but my experience is that it is not wise to use 1/4 in. wedges for all patients indiscriminately. Very few adults will feel comfortable with more than 1/8 in. inside wedges to the heels, while more than 3/16 in. is rarely tolerated; among athletes few need crooking of the sole, and some even need an *outside* wedge to the sole to prevent them slipping over in the shoe and getting a corn on the little toe.

4. *Congenital Subluxation of the Patella.*—In the discussion of quadriceps insufficiency no mention is made of congenital laxity of the ligamentum patellae, moderate degrees of which are quite common and may cause a sudden giving way of the knee that may simulate injury to the semilunar cartilage, but is not a true "locking," though it is usually started by some slip or strain. In a discussion last year in the Orthopaedic Section of the Royal Society of Medicine several of the speakers expressed the view that many knees, which have been opened for supposed cartilage injury and with negative findings, were really instances of this condition.

Trusting that you will allow me some of your valuable space for drawing attention to these points, which are apt to be overlooked in practice, though simple when recognized.—I am, etc.,

M. FORRESTER-BROWN, M.S., M.D.Lond.

Bath, Sept. 13.

Aetiology of Erythema Nodosum

SIR,—The latest theories concerning the aetiology of erythema nodosum relegate this very definite clinical entity to the realm of allergy, and the allergens responsible are said to range from tuberculin to the toxin of haemolytic streptococci. The observations throughout the following case and before the appearance of the eruption would seem to be of value in this regard.

A girl aged 4 years was seen with swollen glands on the right side of the neck. While the swelling was lower than the usual tonsil gland the throat was considered to be the source of infection. Some days later the local lesions of erythema nodosum appeared on both legs in the usual position anteriorly. They continued to appear in crops on the buttocks, the forearms, and on the face, particularly on the forehead, one typical lump being just above the bridge of the nose. The lesions went through the usual stages, showing finally mild ecchymosis. The patient's temperature ranged from 99° in the morning to 103° and 104° in the afternoon. The gland was not very tender, and no sore throat was complained of. There were mild joint pains, but these were not a marked feature.

The temperature subsided after about sixteen days but the swelling remained. A seaside holiday improved the patient's general health, but the gland did not diminish, and since it was causing some torticollis by virtue of its bulk it was removed, when it was found to contain pus. The latter on examination revealed *tubercle bacilli and no other organisms;* section of the wall of the gland showed giant-cell systems of the nature of tuberculous infection. One could safely assume, therefore, that the condition was tuberculous and not a mixed infection.

Nature is usually true to type in her skin manifestations, and erythema nodosum is such a definite clinical entity that one would hesitate to ascribe its causation to such widely differing types of infection as tubercle bacilli and haemolytic streptococci.

This case is so clear cut in its manifestations and pathological findings that one ventures to argue that, short of equally positive findings, erythema nodosum should be considered as of tuberculous origin unless proved otherwise.—I am, etc.,

London, N.7, Sept. 12. W. LEES TEMPLETON, M.D.

Relief of Rheumatic Conditions

SIR,—In a recent letter published in the *Journal* of July 10 (p. 88) I urged the importance of exercises conducted by the patient, rather than massage, for the relief of rheumatic conditions. In this connexion the results obtained by Dr. F. G. Bushnell on himself, and communicated to me, are of interest. Dr. Bushnell was, unfortunately, the victim of a very severe attack of rheumatoid arthritis. The method which Dr. Bushnell adopted for effecting relief could be followed in sanatoria devoted to the treatment of rheumatism in the same way as sanatoria are set aside for the treatment of tuberculosis.

In Dr. Bushnell's case the febrile period lasted about six months, and was spent in bed in hospitals. Dr. Bushnell, who was about 69, carried out such exercises as were possible while at "rest," but no orthopaedic measures, such as splints or correction of deformities under anaesthesia, were advised, and at the end of the febrile period he was left with flexed painful knees and elbows, etc., wasted limbs, and was unable to crawl more than a few yards or to mount steps. Having tried autogenous vaccines and various vaunted pharmaceutical "remedies" without effect, he resolved to assist natural recovery: (1) by exposure of his body to sun and air and by sea bathing; (2) by active and passive exercises of all affected joints and muscles, conducted when warm enough either in the open air or under water; (3) by rest; (4) by a balanced, adequate diet. He obtained the best climatic conditions in the Canary Islands, where there is sunshine daily, an even temperature between 60 and 70° F., and practically no rain. From being in 1934 almost a stretcher case, he is now able to walk slowly some six or eight miles over hilly mule tracks, to "trot" on the sand, and to swim in the sea several hundred yards—an immense improvement. He has found it necessary to work without ceasing for recovery, even to the fatigue point. The objectives are to retain general health, re-educate the muscles, and so overcome deformities. When the acute stage has subsided deformities can be dealt with by manipulation of the orthopaedic surgeon under conditions of anaesthesia, the patient afterwards maintaining the improved range of movement thus given by exercises. As remedial exercises are monotonous, rowing, swimming, cycling, gymnastics, and gardening help to keep the patient cheerful. Dr. Bushnell has found that voluntary contraction of spastic muscles against opposition, however evoked, tends to produce relaxation of such muscles and lessen deformity.

E. B. M. Vance (*Journal*, January 11, 1936, p. 53) described hand exercises, which, if carried out, would diminish greatly the number of stiff hands.

—I am, etc.,

St. John Clinic and Institute of Physical Medicine, Sept. 7. LEONARD HILL.

A Complication of Endoscopic Resection

SIR,—In a recent case of endoscopic resection at All Saints' Hospital a complication was encountered which might be of sufficient interest and rarity to merit publication.

A man aged 74, first seen in July of this year, gave a history of frequent painful micturition and nocturia; he had had several previous attacks of "cystitis." Cystoscopy and urethroscopy revealed a fibrous prostate, only slightly resilient to fluid pressure, with marked median bar enlargement and a trabeculated bladder. Residual urine measured 4 ounces. The posterior urethra was tight, but caused no obstruction to the introduction of a Gehring urethroscope (F 25). An *x*-ray plate revealed the presence of several prostatic calculi.

Pre-operative treatment by bladder lavage with 1 per cent. silver nitrate instillations and posterior urethral dilatation (Kollmann) was carried out. Routine dilatation to Clutton 28/32 preceded the introduction of the McCarthy instrument (F 28). Mr. F. McG. Loughnane resected 5.5 grammes of tissue, removing in all fifteen to sixteen pieces, and during the operation several prostatic calculi were evacuated in the bladder wash. The resectoscope was removed only at the end of the operation. Haemorrhage was minimal. Following irrigation with Mr. Loughnane's two-way rubber catheter for forty-eight hours the urine was clear and the catheter was removed. Convalescence was normal and apyrexial until the fifth day, when the patient complained of tenderness on the dorsum of the penis, at the peno-pubic angle, and rather to the left of the mid-line. The following day he had some loss of tactile sensation in the penis. On the seventh day I evacuated half an ounce of seropurulent fluid under considerable tension from the body of the left corpus cavernosum. The cavity appeared to be entirely limited by the sheath of the corpus, had no demonstrable connexion with the penile urethra, but contained two small prostatic calculi. On the following day the patient passed urine through his sinus as well as per urethram.

The cause of abscess formation is open to speculation, but there are two possible suggestions:

(*a*) That as a result of previous instrumentation mucosal abrasions were formed, with subsequent proliferation of granulation tissue, which may have incorporated two prostatic calculi liberated from the prostatic bed. (*b*) That abscess formation was secondary to a process of infection, extending forward from the prostate and carrying two prostatic calculi in its wake.

Mr. F. McG. Loughnane has kindly authorized publication of this interesting case.—I am, etc.,

All Saints' Hospital, S.E.11, Sept. 7. WILLIAM MICHIE. Senior House-surgeon.

Nutrition in the Falkland Islands

SIR,—On January 16 of this year you published a very interesting article by Dr. Cheverton on an epidemic of influenza on the Falkland Islands, which made me anxious to know something more about the conditions under which our "brothers" the colonists have to live. As a result of my inquiries I have come to the conclusion that under present conditions it is impossible for the islanders to be properly fed and to be A1 people. If Great Britain is to possess colonies, then it must be on the condition that the colonists are able to lead good, strong healthy lives, or, in other words, no colony should be retained at the expense of the community, and especially of the children.

Now it appears that malnutrition is a basic factor in the human beings, cattle, and sheep of the Falkland Islands. The average islander lives on mutton, bread, potatoes, and tea. Vegetables, which are so essential for everybody and especially for growing children, cannot be grown, or, if so, with great difficulty, as the weather, with so little sunshine and so much damp, does not allow of such vegetation. The soil, as Dr. Cheverton states, *is* chiefly peat or clay with some sandy outcrops, whilst trees are almost *nil*, so that the country may be described as bleak and inhospitable. The acid content of the soil is high and the available amount of calcium is *nil*. Such a state of soil combined with limited sunshine is responsible for a poor state of health amongst the children, whose resistance to gastric and respiratory diseases is very low. During the last two years as many as thirty operations for appendicitis have been performed amongst a

population of 2,500. The teeth of the children from 18 months upwards are rotten, and children at school have to wear dentures. The supply of cow's milk is limited, and one cannot hope for good milk from cows fed on such poor, acid soil, although the poor beasts do their best to maintain their strength by going down to the beach to eat seaweed.

The problem for us in Great Britain, and especially for the medical profession, is whether we as a nation are justified in continuing to allow women to give birth to children under circumstances which make it impossible for them to rear them on good healthy lines? Are we to allow the breeding of fragile children for the sake of retaining a colony?

In my opinion the time has arrived when a Royal Commission should be appointed to go into the whole problem of the conditions under which so many of our brothers and sisters who live in our colonial possessions are obliged to pass their lives.—I am, etc.,

Swansea, Sept. 8. G. ARBOUR STEPHENS.

The Shopman's Finger Lick

SIR,—Is it not time for the health authorities to take serious notice of the filthy habit of many shop assistants and others, especially those employed in shops where comestibles are sold, of licking their fingers before taking paper or bags for wrapping the food. To what extent is this habit responsible for the spread of infectious diseases? For every one of such persons may well be a potential carrier. This custom does not exist in every shop, but for all that is fairly common. I have myself walked out of a shop and left the goods on the counter. The habit is filthy, insanitary, and unnecessary, and appears to be a result of ignorance and bad training.—I am, etc.,

Clifton. HUBERT C. BRISTOWE.

The Services

DEATHS IN THE SERVICES

Surgeon Captain ERNEST FITZGERALD ELLIS, R.N. (retired), died at Bridgnorth on August 15. He was educated at University College, London, and took the M.R.C.S. and L.R.C.P. in 1901. Entering the Navy soon after, he attained the rank of surgeon commander on February 11, 1915, and retired as surgeon captain on January 7, 1924. He was appointed final medical examination officer of naval recruiting at Birmingham on May 25, 1926. He leaves a widow and a daughter.

Lieut.-Colonel CHARLES WILLIAM HENRY WHITESTONE, R.A.M.C. (ret.), died at Charmouth on August 23, aged 72. He was born at Waterford on November 27, 1864, the youngest son of the late Berkeley E. Whitestone of Dublin, and was educated at Trinity College, Dublin, where he graduated B.A., M.B., B.Ch., and B.A.O. in 1887. After serving as house-surgeon at Sir Patrick Dun's Hospital, Dublin, he entered the Army as surgeon on January 31, 1891; he became lieutenant-colonel on February 13, 1913, and retired on November 17, 1919. He served on the North-West Frontier of India in 1897-8, when he took part in the campaign on the Malakand, receiving the frontier medal with a clasp; and in the South African War from 1899 to 1902, when he took part in operations in Cape Colony, the Orange River Colony, and the Transvaal, and gained the Queen's medal with three clasps and the King's medal with two clasps.

Lieut.-Colonel GEORGE THOMAS LANGRIDGE, R.A.M.C. (ret.), died at Bournemouth on August 28, aged 88. He was born at Bath on May 9, 1849, was educated at Bart's, and took the M.R.C.S. and L.R.C.P.Lond. in 1871. After acting as house-surgeon at the Seamen's Hospital, Greenwich, he entered the Army as surgeon on September 30, 1873, passing in first. At the Army Medical School at Netley he gained the Herbert prize, and was first officer to receive his commission as surgeon immediately on joining after the abolition of the rank of assistant surgeon. He attained the rank of brigade-surgeon-lieutenant-colonel on July 22, 1896, and retired on August 2, 1899. He served in the second Afghan War in 1879-80, when he took part in the Battle of Charasiah, the two expeditions to Maidau, the affairs at Karatiga, Kila Bahadur Khan, Berai-Badam, the capture of the heights at Yukht-i-Shah, and the defence of Sherpur, receiving the medal with two clasps. He also served in the first Boer War in 1881 with the Natal Field Force, and in the Transvaal campaign. He was a member of the British Medical Association for nearly forty-nine years, having joined on July 28, 1885, and resigned on December 31, 1933.

Major ROBERT HAMPDEN CLEMENT, R.A.M.C. (ret.), died at Southampton on July 23, aged 76. He was born on October 31, 1860, was educated at the Carmichael School, Dublin, and took the L.K.Q.C.P. and L.R.C.S.I. in 1883. Entering the Army as surgeon on August 2, 1884, he became surgeon-major after twelve years' service, and retired on August 3, 1904. He served in the Sudan in 1884, in the expedition up the Nile, and in the South African War in 1900, taking part in operations in the Orange River Colony and receiving the Queen's medal with two clasps. He also rejoined for service in the war of 1914-18, from August 6, 1914.

Major CHRISTOPHER JAMES HEALY, R.A.M.C. (ret.), died in Dublin on June 25, aged 72. He was born in Dublin on October 21, 1864, and was educated at Trinity College, Dublin, where he graduated M.B., B.Ch. in 1887. After filling the post of house-surgeon at the Adelaide Hospital, Dublin, he entered the Army as surgeon-captain on July 28, 1891, became major after twelve years' service, and retired on July 28, 1911. He served in the Tirah campaign on the North-West Frontier of India in 1897-8, when he took part in the Mohmand campaign (medal with clasp), and in the operations in the Bara Valley (clasp); and in the South African War in 1901-2, in the operations in Cape Colony, receiving the Queen's medal with three clasps.

Major THOMAS EDWARD MOLES, R.A.M.C., died at Cairo on July 12. He was educated at Belfast University, where he graduated as M.B., B.Ch., and B.A.O. in 1925, immediately afterwards entering the R.A.M.C. He became major on January 26 last.

Universities and Colleges

LONDON HOSPITAL MEDICAL COLLEGE

The second open entrance scholarship, value £100, offered by the London Hospital Medical College, has been awarded to E. O. Williams of Exeter College, Oxford.

The directors of the Commonwealth Fund of New York have created a number of Commonwealth Fund Service Fellowships, tenable at American universities, not more than five of which will be offered in 1938 to persons holding appointments over-seas under the British Government, the Government of India, or the Government of a British Dominion, Colony, Protectorate, or Mandated Territory. Candidates must be of British descent and not have attained the age of 35 on September 1 of the year of award. They must submit a definite scheme of research work or advanced study to be carried out during their residence in the United States, and must produce evidence of their capacity to pursue it with advantage. Fellowships are tenable for a minimum period of fifteen months and a maximum period of twenty-four months, which will run from the date of departure from the country in which the Fellow is engaged in Government service to the date of his return. Applications, on the prescribed form, must reach the secretary, Commonwealth Fund Fellowships, 35, Portman Square, W.1, by February 1, 1938.

Obituary

GEORGE H. SIMMONS, M.D.

Editor Emeritus, *Journal of the American Medical Association*

We announced last week with deep regret the death on September 2, in Chicago, of Dr. George H. Simmons, who, as Editor of the *Journal of the American Medical Association*, for twenty-five years (1899–1924) rendered outstanding service to medical literature, to medical education, to medical organization, to science, and to the general public welfare. In June, 1924, during the annual meeting of the American Medical Association, he was entertained at a banquet and presented with his portrait painted by Arvid Nyholm: an account of the proceedings appeared in the *British Medical Journal* of September 13 of that year. This valedictory dinner, attended by 500 of the leading figures in American medicine, was regarded as the highest tribute that had been paid to a member of our profession in the United States. To Dr. Simmons more than to any man must be attributed the growth of the American Medical Association and the development of its famous *Journal* during the present century.

George Henry Simmons was an Englishman by birth and lineage. A son of George Simmons, he was born on January 2, 1852, at Moreton - in - Marsh, Gloucestershire, and went to school there. After the death of his parents he lived with his maternal grandfather, Richard Clifford, of the Rye Farm, Sezincote. In 1870 he decided to try his fortunes in America, and entering as a student of the University of Nebraska graduated M.D. from the General Medical College and the Rush Medical College of Chicago. He first practised at Lincoln, Nebraska, and was secretary of the Nebraska State Medical Society from 1896 to 1899. He was the founder of the *Western Medical Review*, and its success no doubt led to his appointment to be Editor of the *Journal of the American Medical Association*, which then had a circulation of about 8,000. The *J.A.M.A.* at that time, in the words of Dr. William J. Mayo, was "mediocre and without much influence, either within or without the medical profession. Its standard for acceptance of original contributions and advertising matter was without perspective or ideals." Under Dr. Simmons's editorship the circulation increased more than ten times, and the influence and prestige of the *Journal* grew in proportion. A few months after his appointment as Editor he was also made Secretary of the Association, and continued in this joint post until 1911, when he resigned the secretaryship and became Editor and General Manager.

In every department of his work George Simmons displayed energy, vision, resource, and leadership, but always with personal self-effacement. The *Journal of the American Medical Association* stands as a monument to his executive ability, his keen sense of justice, and close adherence to principle. Under his inspiration it has long stood for the highest in medical science, in medical education, and in professional ethics. Through it he led the fight against quackery and all forms of pseudo-medical fraud, and its rapidly increasing revenue under his direction enabled the Association to carry on a constructive programme of much value to the medical profession and the public. One of its greatest achievements was the weeding out of the inferior medical schools of former days, whose existence had been a reproach to the profession of the United States.

The testimonial dinner in Chicago on June 9, 1924, when he resigned the editorship of the *Journal of the American Medical Association*, gave an opportunity for public acknowledgement of the debt of American medicine to Dr. Simmons. Striking tributes to him and his work were paid by Dr. Harvey Cushing, Dr. Frank Billings, Dr. William J. Mayo, and Dr. William S. Thayer, and by others who could speak with intimate knowledge of his services as journalist, administrator, and reformer. The same note of admiration and affection ran through all the speeches. In his characteristically modest reply Dr. Simmons said that he had always believed and acted on the principle that the American Medical Association was primarily a scientific organization, with for its chief function the advancement of medical science and practice, and that all its efforts must be directed to the common good of the profession and the public. But, he added, while it was reasonable to boast of what had been done, the task was never ending.

After his retirement from active work, to live in a house on the sea coast of Florida, Dr. Simmons continued to keep a wise and watchful eye on the progress of medicine and the course of medical politics at home and abroad. He spent much time in travel and kept up his custom of paying visits to England in the summer. He was present as an honoured guest at the centenary celebrations of the British Medical Association in 1932, and on his last visit in 1936 called at our headquarters in Tavistock Square to renew old acquaintanceships but did not feel equal to the fatigue of attending the Annual Meeting at Oxford. He was then in his eighty-fifth year, and the infirmities of old age were beginning to tell; but nothing could impair his calm and statesmanlike outlook upon the medical scene or his kindly consideration for those who had the privilege of his friendship.

SIR GEORGE POLLARD, M.D.

The death of Sir George Herbert Pollard on August 27 removes a member of our profession who took an active part in public affairs. Born on October 20, 1864, he studied medicine at the University of Edinburgh, graduating M.B., C.M. in 1886 and taking the M.D., with honours, in 1890. After three more years at Edinburgh, where he acted as assistant to the professor of midwifery, he was called to the Bar by the Inner Temple, and on returning to his native town of Southport was elected to the local bench of magistrates. In 1896, the Diamond Jubilee year, he was mayor of Southport, and after two unsuccessful contests was elected in 1906 M.P. in the Liberal interest for the Eccles Division of Lancashire, sitting in the House of Commons for that constituency until 1918. During the war he was a medical adviser to the Ministry of Munitions on poison gas and chemical warfare, and a member of the Ministry's medical board. He received the honour of knighthood in 1909.

Sir George Pollard had been a member of the council of the London Dermatological Society and a vice-president of the Industrial Diseases Section of the Royal Institute of Public Health. He was also for some years a member of the Lancashire County Council. He married Charlotte Elizabeth, daughter of the late Thomas Butterworth of Burnley, who survives him.

Medical News

The annual dinner of the St. George's Hospital Medical School will be held on October 2, at 7.45 p.m., at the May Fair Hotel.

The annual dinner of past and present students of Charing Cross Hospital Medical School will be held at the Café Royal, Regent Street, W., on Saturday, October 2, at 7.30 for 8 p.m.

The annual dinner of the Westminster Hospital Medical School will be held at the Park Lane Hotel on Saturday, October 2, at 7.30 for 8 p.m.

The inaugural address at the London (Royal Free Hospital) School of Medicine for Women (University of London) will be delivered by Mr. H. L. Eason, C.B., C.M.G., in the Albert Levy Hall, Royal Free Hospital, on Friday, October 1, at 3.30 p.m.

The fifteenth annual meeting of the Academy of Physical Medicine will be held at the Hotel Walton, Philadelphia, on October 19, 20, and 21. The Academy, which is international in scope, will present a scientific programme based on reports of the most recent research and the newer techniques in physical medicine as they relate to the practice of the various specialties. In addition to the lectures, demonstration clinics will be held at the hospitals of the University of Pennsylvania, Jefferson Medical College, and Temple University. A copy of the programme may be had from Dr. William D. McFee, 41, Bay State Road, Boston, Mass.

The annual general meeting of the Invalid and Crippled Children's Society will be held at the Invalid and Crippled Children's Hospital, Balaam Street, Plaistow, E.13, on Tuesday, September 21, at 11 a.m., under the presidency of Sir Reginald Kennedy-Cox. A further £5,000 is still required for the proposed extensions of this hospital.

The two-hundreth anniversary of Bristol Royal Infirmary will be celebrated on October 22. At 5 p.m. members of the staff, students, and nurses are invited to inspect the alterations in the buildings and equipment, tea being provided. In the evening there will be a dinner at the University Union (tickets 13s. 6d., exclusive of wines), and it is hoped that as many as possible of the Infirmary's friends and supporters, with guests, will attend. In commemoration of the event a bronze replica of the Infirmary medal is to be issued. All who intend to be present at either or both of these ceremonies should communicate with the Secretary not later than September 30.

An international congress of the history of sciences will be held at Prague from September 24 to 28.

The sixtieth international postgraduate course will be held in Vienna from September 27 to October 10. Special reference will be made to advances in therapeutics. Further information can be obtained from the Kursbüro, Allgemeines Krankenhaus, Alsterstrasse 4, Vienna.

The forty-sixth French Congress of Surgery will be held at the Paris faculty of medicine under the presidency of Professor Gregoire from October 4 to 9 when the following topics will be discussed; pathogenesis and treatment of the immediate and late complications of embolism, pathology and treatment of recent burns of the skin, indications for operation and orthopaedic treatment of simple fractures of the leg and their results. Further information may be obtained from M. A. Vulliod, 12, Rue de Seine, Paris (6e).

The fifth congress of the Association of Scientific Photography and Cinematography will be held in Paris at the International Exhibition from October 7 to 9. Details of the programme may be obtained from Dr. C. Claoue, Rue Scheffer 39, Paris XVI.

A conference on the problem of malnutrition organized by the Council of Action for Peace and Reconstruction will be held in the Memorial Hall, Manchester, on October 2. The secretary of the conference is Miss Hilda Buckmaster, warden of the Ellis Llwyd Jones Hall.

The annual meeting of the German Dermatological Society will be held at Stuttgart from September 18 to 22, the chief subject for discussion being the significance of cutaneous tests.

A home for the treatment of post-encephalitic Parkinsonism is being endowed by Sir Alfred Law at Sparthfield, formerly the residence of the late Sir James Jones. The home will provide accommodation for thirty patients, and those who cannot afford fees will receive free treatment. It is understood that the benefactor decided to endow the home as a result of the work of Dr. C. C. Fenwick and Dr. Neuwahl on what has become known as the Bulgarian treatment of post-encephalitic Parkinsonism.

The September issue of the *Edinburgh Medical Journal* is a special education number.

The issue of *Paris médical* for August 7 contains an illustrated review of Dr. Lévy-Valensi of the history of French medicine as portrayed at the Paris Exhibition.

September 7 marked the centenary of the birth of Professor Hermann Schwartze of Halle, one of the pioneers of otology in Germany, who has given his name to the mastoid operation.

Dr. C. L. Park, Director of the League of Nations Far Eastern Health Bureau, is on his way to Hong Kong to confer with the authorities there on the measures to be taken in connexion with the outbreak of cholera.

Lieut.-Colonel E. D. Caddell, *M.C.*, late R.A.M.C., has been appointed, and has now taken up his duties, as secretary-general of the National Association for the Prevention of Tuberculosis, at Tavistock House North, Tavistock Square, London, W.C.1.

In Austria women number 665, or 9 per cent., of the medical practitioners, 138, or 13 per cent., of the dentists, and 314, or 19 per cent., of the pharmacists.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House, Tavistock Square, W.C.1.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.* SECRETARY, *Medisecra Westcent, London.*

The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh), and of the Office of the Irish Free State Medical Union (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone 62550 Dublin).

QUERIES AND ANSWERS

Lymphatic Oedema

"G.P." writes: I should be much obliged for information as to the treatment of this case of lymphatic oedema. The patient is a woman aged 35, both of whose ankles and legs swell very much on walking even a moderate distance; no pitting on pressure. The oedema subsides on resting for a time. She becomes very short of breath on slight exertion. Her height is 5 ft. 2 in. and her weight 12 st. 3 lb. In spite of a very small appetite and avoidance of everything that might put on weight she is getting stouter. Thyroid has been tried, but without benefit so far. The patient suffers from menorrhagia monthly. She used to work in a canteen, standing for twelve hours a day.

Facial Hirsuties in the Female

"RAYCUS" writes: Will any reader kindly give experience and details of treatment of facial hirsuties in the female by endocrine extracts?

Otitis Externa from Swimming Pools

Mr. ALFRED MERRIN, in reply to Dr. R. S. Gilchrist (*Journal*, August 21, p. 401), writes: Some years ago you published a letter from me in which I recommended the use of fibrous plasticine for ear plugs. I have used these plugs myself, and have found that they absolutely prevent water from entering the ears when swimming or diving. If Dr. Gilchrist will write to "Harbutts," 56, Ludgate Hill, London, E.C.4, enclosing 8d., and asking them to send a tin of fibrous plasticine, he will receive sufficient to last him many years. A portion of the plasticine should be fashioned into the shape of a tack and then inserted in the ear, the point foremost and the head well flattened against the ear. Pressure with the forefinger behind the ear will loosen the plug sufficiently to enable it to be withdrawn. The same plug can be used indefinitely.

Mr. L. A. RIDDELL (Cornwall) writes: When living on a little tropical island some years ago I became afflicted with a painful otitis externa due to frequent swimming in the open sea. Consultation of Castellani's *Tropical Medicine* suggested that it was a mycotic infection due to repeated maceration of the skin of the external ear. The treatment suggested was the application of "nascent iodine," formed (it was said) by the simultaneous use of sodium iodide and hydrogen peroxide locally. For some reason or other I tried to simplify the treatment and used a 1 in 3 watery dilution of tr. iod. mitis. This was applied with thin wisps of cotton-wool on a fine probe—the use of any stouter instrument being precluded by the great swelling of the skin of the meatus, which is a noticeable feature of the condition. The treatment is painful at first but it gives speedy relief, and I treated successfully not only myself but several others. Swimming can soon be resumed, and any relapse (which is very common once the condition has been acquired) can be nipped in the bud as a rule by just one application overnight whenever the tell-tale itching or wetness of the meatus appears.

Income Tax

Loss on Professional Year

"FORD," writing from the Irish Free State, explains that he is allowed cost of replacement of a car instead of depreciation. If that allowance exceeds the profit, can a refund be claimed for past years?

*** No. The cost of replacement is regarded as a professional expense of the year in which the car was replaced and cannot be given effect as regards prior years. The loss—that is, the excess of the cost of replacement over the year's earnings—can, however, be carried forward against future years.

Honorarium

"A. B. C." has been acting as honorary consulting surgeon to a hospital, receiving annually a gratuity of £50, and has understood that acceptance of the "gift" did not in any way prejudice his honorary position. Is the £50 liable to income tax?

*** In our opinion—yes. The scope of the charge under Schedule E is wide: tax is assessable in respect of "every public office or employment of profit," and the section includes as income "all salaries, fees, wages, perquisites, or profits whatsoever." "A. B. C." undoubtedly holds an office or employment, and the honorarium appears to be within the above description. The £50 is apparently not specified in any contract of office, but the fact that it is paid annually, and that the office was accepted and held in those circumstances, takes it out of the category of a "gift."

LETTERS, NOTES, ETC.

Buccal and Lingual Ulcers

Mr. HERBERT TILLEY, in replying to "Puzzled" (*Journal*, September 11, p. 564) writes: In the absence of any description of the ulcers one presumes that they are discrete, pale, superficial, and very sensitive to touch or even to the passage of liquids and semi-solid foods. Furthermore, perhaps it may be assumed that the ulcers have failed to respond to general treatment and to such local applications as silver nitrate, copper sulphate, etc. If these surmises be correct, it is more than probable that the lesions are caused by a deficiency of vitamin A and possibly D, in the patient's ordinary dietary. During the past two years three similar cases have come to notice, and, like "Puzzled's" patient, mine were also females who had proved equally resistant to medicinal and climatic treatment. But each of them responded quickly to preparations containing cod- or halibut-liver oils which are particularly rich in the first-mentioned vitamin. In addition to these remedies, the patients were urged to take an ample supply of egg-yolk and fresh green vegetables. In two of my patients intramuscular injections of campolon (Bayer)—a highly concentrated extract of cod and halibut oils—were followed by complete disappearance of the ulcers within three days! It may not be without significance that the four cases with which this note is concerned were females, and maybe their susceptibility to "buccal and lingual ulcers" is due to their addiction to the carbohydrate elements of foodstuffs, especially when presented in their most attractive forms and consumed frequently with ample quantities of tea. Man cannot live on bread alone!

Corrigendum

Cork Street Fever Hospital, Dublin

Our attention has been drawn to the omission of reference to Cork Street Hospital in the summary of Dublin teaching hospitals in our Educational Number (September 4). The hospital, founded in 1801, is one of the oldest fever hospitals in the British Isles, and is the largest teaching fever hospital (280 beds) in the Irish Free State. It is recognized by the National University, Trinity College, and the Irish Conjoint Board for undergraduate and postgraduate instruction, classes for medical students being held each term, and for D.P.H. students during the winter term.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

209 Bilateral Lingual Atrophy in Tabes

According to M. FELICI (*Riv. Sper. Freniat.*, June 30, 1937, p. 315) lingual hemiatrophy is uncommon and bilateral lingual atrophy extremely rare in tabes. He records three cases diagnosed as tabes in which both sides of the tongue were atrophic and showed fibrillary tremor; one had already had antisyphilitic treatment and admitted infection, but all had negative Wassermann reactions in the blood and cerebrospinal fluid. Two patients had muscular atrophy of the Aran-Duchenne type in the upper limbs. All had laryngeal crises, two had palatal paresis, one had laryngeal palsy, and one weakness of the masseters; such an "inferior bulbar syndrome" is always present when there is bilateral lingual atrophy. This condition, although possibly due to diffuse vascular meningomyelitis, may be attributed among other things to primary degeneration of the hypoglossal nuclei.

210 Enteric Fever

A. BOULET (*Thèse Paris*, 1937, No. 379) records his observations on 111 cases treated at the Val-de-Grâce Military Hospital, Paris, from 1926 to 1936. Of these, forty-four were cases of typhoid, nine of paratyphoid A, and fifty-seven of paratyphoid B, and in one the type was not stated. The majority had been inoculated several months before their attack, a few only a month or less before, and ten several years previously. In most of the cases the disease was mild. In ninety-four patients the febrile period did not exceed twenty days, and in nine it ranged from two to five days. Only eight cases had complications, myocarditis in three and intestinal perforation in one proving fatal. In the surviving group there was phlebitis in one and slight intestinal haemorrhage in three. Of the four deaths, two were due to typhoid, one to paratyphoid A, and one to paratyphoid B, giving a mortality of 4.5, 11.1, and 1.7 per cent. respectively for the three groups, and a total mortality for the 111 cases of 3.6 per cent.

211 Epidemic Myalgia

R. R. MACDONALD, B. HEWELL, and M. L. COOPER (*Amer. J. Dis. Child.*, June, 1937, p. 1425) report their observations on seventy cases of epidemic myalgia investigated at the Children's Hospital, Cincinnati, from July to October, 1935. During this period 282 cases were reported to the local department of health. The outstanding symptoms were pain (most commonly abdominal) and fever, both of which were sudden in onset. Twenty-five blood cultures taken from twenty-three patients were persistently negative, and spinal fluid cultures taken from three patients also remained negative. Throat cultures showed a variety of bacteria, but the only constant micro-organism was a slightly haemolytic streptococcus, which was also found in cultures taken from nasal swabs.

212 Early Symptoms of Acute Coronary Occlusion

SAMPSON and ELIASER (*Amer. Heart J.*, June, 1937, p. 675) have found that a single spontaneous attack of prolonged anginal pain strongly suggests the approach of a typical coronary thrombosis. The pain may be due to the sudden blockage of an artery which has been gradually narrowed to an extreme degree. In twenty-nine cases observed over a period of two and a half years the authors found that long-standing angina pectoris was present in about 50 per cent. The character of the premonitory attack of precordial pain in those patients who had had angina pectoris previously rarely differed from their former pain. The duration of the premonitory syndrome varied from two minutes to two hours, the average being one hour. The interval between the attacks varied between one and twenty-one days, but was usually a week. Electrocardiograms offered no assistance in the diagnosis of impending thrombosis. Records taken after the occlusive attack naturally showed characteristic pathological changes. A mortality of 35 per cent. was found in patients who had experienced the premonitory syndrome. The authors decide that it is still doubtful whether rest in bed increases the chances of survival in patients in whom the premonitory symptoms have been diagnosed. These may occur characteristically in patients who fail to develop typical signs of a coronary artery occlusion within a period of some weeks afterwards. Six patients who had a severe attack of pain were placed at complete rest and within one to three weeks their attacks had completely subsided. It is possible that occlusion was forestalled and that a collateral arterial supply developed in these cases.

Surgery

213 Chronic Portal Obstruction

V. LOZZI (*Rinasc. med.*, June 15, 1937, p. 371), after an allusion to the non-success of the usual surgical treatment of ascites in hepatic cirrhosis, considers the various venous anastomoses which have been effected. He remarks that Rosenstein's union of the inferior vena cava and the portal vein demands virtuosity even in a surgeon experienced in vascular operations, and regrets that anastomosis between the superior mesenteric and portal veins, as done by Bogoraz in 1912 and Krestiowsky in 1926, has not more often been tried. He has found that such a union remained pervious in seven out of ten dogs. The same operation has been done on an alcoholic subject, aged 49, with hepatic cirrhosis, and in a woman, aged 26, with portal thrombosis. Both made good recoveries, and the rate of accumulation of ascitic fluid was afterwards considerably less. Lozzi prefers a lateral anastomosis to the termino-lateral union made by the others, and regards a stoma of at least 15 mm. in diameter as essential. A less drastic proceeding proposed by the author is anastomosis of a radicle of the inferior mesenteric vein or of the ileocolic vein with an iliac vein; this method was tried by Ghiron without success.

214 Indications for X-Ray Therapy

H. HOLFELDER (*Wien. klin. Wschr.*, July 16, 1937, p. 1051) gives the results of his extensive experience in the treatment of malignant growths with *x* rays, and compares them with those obtained by operation. In small carcinomata of the skin surgery and irradiation give equally good results, whereas extensive inoperable skin carcinomata can be treated only by irradiation. The proportion of recurrences in these cases was only 20 per cent. Of cases of inoperable carcinoma of the breast treated with *x* rays, 40 per cent. were alive after three years, and 36 per cent. after five years. Prophylactic post-operative irradiation considerably improved the operative results; 68 per cent. of cases treated in this way were alive after three years and 54 per cent. after five years. Untreated bronchial carcinoma practically always proves fatal, but three cases treated with *x* rays were alive after seven, six, and four and a half years respectively. Similar results were obtained in cases of carcinoma of the oesophagus, in the treatment of which the author prefers *x* rays to intra-oesophageal applications of radium. *X*-ray treatment cured 5.5 per cent. of cases of inoperable carcinoma of the stomach, and an improvement was effected in 42 per cent. of all the cases treated. In lymphogranulomatosis *x*-ray

treatment considerably retarded the inevitable fatal issue. In pituitary tumours a clinical cure was obtained in 50 per cent. of cases, and the author thinks that in spite of the excellent operative results treatment by irradiation is preferable in these cases. A five-year cure in cases of osteogenetic sarcomata was obtained in 23 per cent. of cases by *x* rays alone, and in 31 per cent. by combined surgical and radiological treatment. The author stresses the importance of the collaboration between surgeon and radiologist in the treatment of malignant growths.

215 Statistical Study of Appendicitis

K. ÖSTERBYE (*Ugeskr. Laeg.*, July 8, 1937, p. 729) of Aarhus, Denmark, notes that the mortality from appendicitis, is nearly twice as high in Denmark, where some 4,000 cases of acute appendicitis are operated on every year, as it is in Norway and Sweden. This striking difference may be due to the differences in treatment, in the interval between the onset of the disease and operation, or in the dietaries of the Scandinavian countries. He suggests that further light could be thrown on this problem by the adoption of a standard method of classifying and recording results. He has set an example in this respect by comparing his own cases for the ten-year period 1926 to 1935 with the cases from Bispebjerg, Denmark. The Aarhus cases numbered 1,143, the Bispebjerg cases 2,038. The corresponding numbers operated on were 1,121 and 1,697 respectively; thus in Aarhus the percentage of cases operated on was much higher than in Bispebjerg, where Group III cases (Bauer's classification of 1910) of acute appendicitis with circumscribed suppurative peritonitis were treated conservatively. The three measures which distinguished the treatment of the Aarhus cases from that of the Bispebjerg group were as follows: (1) the cases were operated on irrespective of the group to which they belonged and of the duration of the disease; (2) drainage was only rarely resorted to; and (3) there was no post-operative treatment with opium. The mortality in Aarhus was 5.86 per cent. for all the cases, and 5.80 per cent. for all those treated by operation. The corresponding figures for Bispebjerg were 5.99 and 6.42 per cent. respectively. The author comes to the conclusion that he has been justified in his operative policy, chiefly because in early cases it is impossible, by means of the diagnostic tests at present available, to distinguish Bauer's Group I cases of acute appendicitis without peritonitis from Group III cases with circumscribed suppurative peritonitis.

Therapeutics

216 Physical Hyperthermia

F. WALINSKI (*Zbl. inn. Med.*, July 17, 1937, p. 593) has been using physical hyperthermia for ten years. Each patient was given 10 c.cm. of a 20 per cent. sodium chloride solution intravenously, and was then placed in a bath the temperature of which was 36° C., rising to 42° C. within ten to thirty minutes. Finally he was wrapped in a flannel jacket and five woollen blankets. The number and duration of treatments depended on the disease. Diseases of the central nervous system required from four to six hours, and cases of arthritis needed from one-half to three hours. The presence of cardiovascular and renal disease contraindicate the treatment, which has been applied to 534 cases, with no deaths. The sodium chloride inhibits sweating. With a rise of temperature the sodium chloride content of the blood increased, the blood pressure rose, acidosis occurred, there was a leucocytosis, and the blood sedimentation rate was usually increased. The blood sugar fell while the patient was in the bath, and then rose later. The author found that hyperthermia was as successful as malarial treatment in cases of tabes and cerebral syphilis, and in elderly or debilitated patients it was the treatment of choice. It had no effect on post-encephalitic Parkinsonism, myelitis, or amyotrophic lateral sclerosis. The results obtained in 159 cases of chronic arthritis were excellent. In seven cases of gonorrhoea in females six were cured without further local treatment; ten cases with inflammation of the adnexae were completely cured. The author believes that it is the high body temperature alone which accounts for the success of this therapy.

217 Gas Gangrene Therapy

A. BORCHARD (*Zbl. Chir.*, July 24, 1937, p. 1746), in spite of failures, believes that the best treatment for gas gangrene is the prophylactic administration of anaerobic serum. That even small lacerations may be the cause of this condition is illustrated in one of the author's cases, which developed a severe infection following a slight abrasion of the outer side of the little finger. The patient was admitted one and a half days after a bicycle accident, seriously ill, and with a high temperature and rapid pulse. Amputation or even disarticulation of the arm was out of the question. Borchard made a circular incision round the pectoral muscle and scapula, and down to the fifth rib a hand's breadth from the infected area. All the areas in which gas could be detected were incised, and hydrogen peroxide tampons were applied to each incision and constantly renewed. Large doses of anaerobic serum, cardiac stimulants, and oxygen inhalations were administered. Fresh incisions had to be made during the first fortnight as new accumulations of gas were discovered, but the patient was discharged after three months with all incisions completely healed. The author thinks that general treatment, while unable to overcome the infection alone, played an important part in raising the body's resistance. He is doubtful whether fascial incision, walling off the infected area from the healthy tissues, obstructs every route of infection, but he recommends a trial of this procedure, which can, if necessary, be followed by amputation.

Dermatology

218 Pituitary Hormones in Skin Disease

G. PIGHINI (*Policlinico*, Sez. Prat., July 5, 1937, p. 1293), who had previously shown the close relation between the skin and the neuro-hormonic system especially the hypophysis, records his observations on ten cases of alopecia areata, four of acne vulgaris, and two of acne rosacea treated by intramuscular injections of extract of the anterior lobe of the pituitary. Of the ten cases of alopecia areata seven were completely cured, two showed some improvement and were not followed up, and one showed no change. Two of the cases of acne vulgaris were completely cured and two showed considerable improvemen. The cases of acne rosacea were also completely cured The pituitary treatment was combined with the administration of thyroid and iodine to counteract excessive pituitary stimulation. Injections of 1 c.cm. of the extract were given for about twenty-five days, followed by an interval of a week and then resumption of the treatment.

219 Ringworm

E. S. DOWDING and H. ORR (*Brit. J. Derm. Syph.*, July, 1937, p. 298) examined tissue from about 200 patients in Alberta, Canada, and found that *T. gypseum* was responsible for 67 per cent. of ringworm. A culture of this fungus was obtained from scales taken from the fingers of a patient with ringworm of the hand, and this strain was used as a type culture. Fifteen other cultures isolated from patients with three different types of ringworm were identified as *T. gypseum*. The first group of seven patients showed vesicular lesions of the glabrous skin of the hand, wrist, arm, or shoulder. In the second group there were five patients with chronic, scaly, and sometimes vascular

lesions of the skin of the feet. In the third group there were three patients with pustular, boggy, nodular lesions of the beard, with some hair infection. Nine of the sixteen cultures of *T. gypseum* differed from the type culture in texture or colour of the mycelium, in pigmentation of the nutrient medium, or in microscopical characteristics such as the absence of macroconidia. No correlation existed between the clinical type of ringworm caused by the fungus and the variation which it exhibited on Sabouraud's medium.

220 Local Treatment of Leg Ulcers

A. TZANCK and M.-L. NERET (*Bull. Soc. franç. Derm. Syph.*, June, 1937, p. 993) describe four cases of varicose leg ulcers cured by the application of an ointment containing flounder oil (*l'huile de flétan*). The dressings were first renewed daily and later every three or four days. During the treatment the patients were confined to bed. The authors claim that the vitamin A content of this oil is greater than that of cod-liver oil. An ulcer measuring 6 cm. by 3 cm. healed in three weeks, and another measuring 3 cm. by 1 cm. healed in eighteen days. In all four cases reported other means of treatment had previously been tried with no result. The authors have been using the same treatment in a variety of other skin conditions, including eczema, lupus, etc., with encouraging results.

221 Exudative Erythemata

K. BINGOLD (*Med. Klinik*, July 2, 1937, p. 889) describes erythema exudativum multiforme as a general disease in which the skin condition predominates. Erythema infectiosum and nodosum are two clinical subdivisions of this disease. Aetiologically, syphilis, influenza, lymphogranulomatosis, and septic conditions must be borne in mind. In gonococcal endocarditis a polymorphous exanthem may be present. In mild as well as in severe cases of sepsis due to staphylococci eruptions may be found over the whole body, and in the earliest stage there is oedema of the papillary bodies and the cutis. Miliary abscesses appearing as papules occur in the stratum reticulare. In sepsis due to pyogenic haemolytic streptococci the skin is covered with papules which sometimes become pustular. Haemorrhages, roseoles, pustules, and widespread erythemata may occur together. In endocarditis due to pneumococci metastatic skin conditions are uncommon. In meningococcal infections of the skin the arteries and capillaries are affected; the clinical picture of erythema exudativum and nodosum may be seen, and roseoles and petechial or haemorrhagic exanthemata may be found. In endocarditis lenta bacterial emboli are found in the end-arteries of the skin, producing painful Osler's nodes. *B. pyocyaneus* produces an inflammation of the arterial wall resulting in a red wheal, which may become ulcerated. In all cases of erythema accompanied by a high temperature a blood culture should be done.

222 Gonococcal Epididymitis Treated by Leeches

M. SCHUBERT (*Derm. Wschr.*, July 17, 1937, p. 917) has been using leeches in the treatment of gonococcal epididymitis since 1936 with good results. Three leeches were applied as soon as this complication occurred, and within half an hour they fell off, engorged with blood. There was bleeding from the site of suction for about three hours afterwards. During the treatment rest in bed with the scrotum raised and applications of boric fomentations were ordered; urethral injections were stopped. Thirty-six patients treated in this way were compared with thirty-five treated in 1935 by other methods. The author found that: (1) treatment with leeches relieved pain more quickly than did other methods; (2) the inflammatory swelling did not regress as rapidly as the pain; (3) urethral injections could be resumed a few days earlier than in other treatments; (4) the average course of treatment could be shortened by a week. In 83 per cent. of cases the condition on discharge was excellent, and in 17 per cent. it was unsatisfactory. Schubert used leeches in five cases of gonococcal arthritis and in eight cases of non-specific epididymitis, and had surprisingly good results. He believes that the value of leeches lies in their restoring normal circulatory conditions; pain is thus relieved and spasm of the blood vessels inhibited.

223 Ultra-violet Irradiation in Skin Diseases

A. A. BABKOVA (*Arch. Sci. biol.*, 1937, 45, 1, p. 207) has investigated the sensory and motor chronaxia before and after the action of ultra-violet light in various types of skin diseases, including eczema, dermatitis, lupus erythematosus, lupus vulgaris, and dermatomycosis. She noted regular changes in the sensory chronaxia beyond the limits of one segment. The nature of these changes was determined by the functional state of the nervous system before irradiation; the healthy skin showed a lengthening of the chronaxia, while in the affected skin the previously lengthened chronaxia was shortened. The functional changes were identical in the different skin affections irrespective of the aetiology and clinical symptoms.

224 Poradenitis Venerea

T. HASHIMOTO *et al.* (*Jap. J. Derm. Urol.*, May 20, 1937, p. 165) have studied 185 cases of poradenitis venerea (lymphogranuloma inguinale) since 1928, 171 in men and 14 in women; 82 per cent. of the patients were in the third decade. In all but three the disease was of venereal origin. In 114 the primary lesion was found on the external genitalia. It occurred as a circular erosion with no infiltration, or as an irregular sore the size of a pea, or as rounded, hard, infiltrated nodules, with central depressions, slightly raised above the skin surface. The incubation period of the primary lesion was a week in seventy-five cases, and it lasted from one to forty days. Unilateral buboes were slightly more common than bilateral, the right and left sides being equally affected. The incubation period of the buboes was most commonly from two to four weeks. Frei's intradermal reaction was specific in 96 per cent. of cases. The duration of the disease depended on the degree of glandular inflammation; the shortest duration recorded was eighteen days and the longest 390, the average being from two to three months.

Obstetrics and Gynaecology

225 Bilateral Hydrosalpinx

C. BÉCLÈRE (*Bull. Soc. Obstét. Gynéc. Paris*, May, 1937, p. 381) again emphasizes the clinical importance of bilateral hydrosalpinx, which is usually only detected radiologically. The condition is more common than is usually supposed, and Béclère found it in 100 out of 800 cases which he investigated for tubal impermeability by lipiodol injections, and these were all gynaecological patients in whom diagnosis was difficult. In his personal experience of cases of sterility about one-quarter have bilateral hydrosalpinx, this representing one-half of those with bilateral tubal occlusion; the corresponding proportions in chronic genital infection are one-seventh and one-third respectively. The condition is less common in cases of metrostaxis without obvious cause and cases of intermenstrual pain, in both of which bilateral hydrosalpinx may be an incidental expression of a chronic infection. The cause in two-thirds of cases is a genital infection which has been chronic from the beginning and is nearly always gonorrhoeal; other cases are infection after labour or abortion, tuberculous infection—often occurring after ascites in childhood and diagnosed only by

microscopical examination of the specimen—and rarely, an acute peritoneal infection as in appendicitis. Clinically there are no decisive objective or subjective signs, but bilateral hydrosalpinx may be suspected when acute salpingitis has followed a gynaecological examination or manœuvre, when adnexal swellings disappear, and when treatment by diathermy in a chronic infection fails. Intermittent hydrorrhoea is only an initial and uncommon sign. Radiographic detection demands a supplementary plate made twenty-four hours after lipiodol injection, and important signs are the well-defined spherical droplets in the tube away from the middle line on both sides, and a precise and clean tubal shadow. The collections of fluid may remain unchanged for many years, but after reinfection or trauma they may turn into a pyosalpinx; they may also be subject to repeated subacute inflammatory attacks. In the presence of hydrosalpinx cervical dilatation or cauterization may provoke acute symptoms, and it is best to abstain from diathermy.

226 Pregnancy following Operative Sterilization

K. W. SCHULTZE (*Zbl. Gynäk.*, July 17, 1937, p. 1683) has collected from the literature thirty-two cases in which pregnancy occurred after occlusion of the tubes for the purpose of sterilization, and he also reports five cases of his own. In one of these the round ligament had been mistaken for the tube; in another a fistula had formed between the ovary and the tube following a partial salpingectomy.

227 Metritis and Diathermy-coagulation Therapy

C. MOUSSALLI (*Gynécologie*, May, 1937, p. 282) describes a special electrode for intra-uterine coagulation of the uterine mucous membrane in cases of metritis. The active part of the electrode is a short thin insulated rod which carries two crescentic platinum electrodes, each connected to a different terminal of the diathermy apparatus. The rod can be rotated and at the same time made to penetrate deeper into the uterine cavity. In this way the whole of the mucous membrane can gradually be coagulated. No special preparation of the patient and no anaesthesia is required. The coagulated mucous membrane gradually separates, and the healing is complete in about three weeks. The author has not met with a single accident in the 400 cases treated by this method.

Pathology

228 Biological Tests for Pregnancy

F. A. E. CREW (*Amer. J. Obstet. Gynec.*, June, 1937, p. 989), reporting from the Pregnancy Diagnosis Station, Edinburgh, calls the biological tests for pregnancy "weapons of precision." The Friedman test with rabbits is quicker and more delicate although more expensive than the Aschheim-Zondek test with mice. The Friedman test is done with two rabbits in medico-legal cases and combined with the Aschheim-Zondek in cases of suspected ectopic gestation. The Aschheim-Zondek becomes negative seventy-two hours after the expulsion of the embryo. Series of observations by Aschheim-Zondek tests enable varying diagnoses to be made according to the degree of reaction observed. For the diagnosis of foetal death the tests are not reliable, nor can they be trusted before one month after conception, or in unmarried girls aged from 13 to 17, or in women over 43. Uterine enlargement in mice when the ovarian blood spots are absent indicates very early pregnancy, idiopathic low hormone concentration, menopause, incipient menstruation after a period of amenorrhoea, recent death of the ovum, or some endocrine disturbance not connected with pregnancy. Repetition of the test ten days later may be necessary. Toxic specimens, usually after attempted abortion, killed thirty-four of the mice. Tests for hydatidiform mole were made by diluting the urine. After the removal of a mole the test becomes negative in three months unless chorion epithelioma has supervened or spread. It is therefore of value for differential diagnosis as well as in such conditions as tuberculosis, peritonitis, ovarian cyst, etc. Quantitative estimations of oestrin and gonadotropic and male hormones in blood and urine are undertaken at the laboratory. The results are not at present of great clinical value, but experience will make them of more than academic interest. Professor Crew points out that the laboratory reports are to be read by the clinician as evidence for diagnosis and not as being themselves indisputable. He also insists that the clinician must use the laboratory reports not as a final diagnosis but as a contribution towards it.

229 Polypeptidaemia in Pulmonary Tuberculosis

G. TOSI and E. LENCI (*Riv. Patol. Clin. Tuberc.*, June, 1937, p. 413) recall that the presence of polypeptides in the blood to the extent of 2 to 4 per cent. in physiological conditions is independent of alimentary protein digestion. In febrile and cachectic conditions a notable increase is encountered as an expression of increased endogenous tissue metabolism, but no clear connexion of hepatic disease, renal disease, or uraemia followed by hyperpolypeptidaemia has been made out. In an analysis of seventy-two cases of pulmonary tuberculosis they found that the estimation of the blood polypeptides in connexion with other methods of physical examination furnished a valuable aid to prognosis. In the "inactive" cases, most of which gave definite evidence of fibrosis, there was a slight increase; in "active" or evolutive cases a notable hyperpolypeptidaemia was usually found. The figures were in no way proportional to the degree of pyrexia or to the abundance of sputum.

230 Serological Diagnosis of Syphilis

O. SIEVERS (*Finska LäkSällsk. Handl.*, May, 1937, p. 395) reports from the Sero-Bacteriological Institute of the University of Helsingfors his experiences with 3,575 samples of blood taken from 3,025 patients. The Streng-Murto modification of Wassermann's reaction was employed, and its findings were compared with those of Kahn's "flockingsreaktion" and Müller's "Ballungsreaktion II" (KR and MBR II respectively). It is now generally agreed that the supplementing of Wassermann's reaction with one or both of the above-mentioned reactions is desirable. In 551 cases of syphilis the sera yielded mutually confirmatory reactions to KR and MBR II in 95.9 per cent. With regard to the cases in which the findings of the reactions were divergent, KR was positive and MBR II was negative in twenty-three cases, whereas in twelve KR was negative and MBR was positive. In most of these thirty-five cases of conflicting evidence the patients had already received specific treatment for syphilis. In 98.7 per cent (2,089 cases) of the control cases KR and MBR II confirmed each other, and in forty-four cases positive reactions were obtained with both these tests. The author defers to a later publication his discussion of these possibly misleading reactions in presumably non-syphilitic persons, associating this problem with that of non-specific positive Wassermann reactions. Of the twenty-seven samples of blood which reacted differently to KR and MBR II, twelve gave a positive reaction to the former and a negative reaction to the latter, while the reverse was the case with the remaining fifteen. The author is highly satisfied with the conformity of KR and MBR II, but as a matter of routine he employs both in the hope of avoiding mistakes. He repeats both tests when they are mutually contradictory if the blood is not taken from a definitely syphilitic patient. When both reactions are positive and Wassermann's reaction is negative he advises the continuous supervision of the patient.

SPRAY ARGYROL IN COMMON COLD

BRAND SILVER VITELLIN

At this time of year, with frequent exposure to cold and wet, the common cold takes on a more serious aspect. Tonsillitis, pharyngitis and sinusitis are frequent sequelae when "dread Winter spreads his latest glooms."

The prevention of complications is the first aim of the physician. Early treatment with Argyrol Brand Silver Vitellin not only attacks the infection right at its source, but also quickly relieves the acute distress in the respiratory tract.

The Dowling Argyrol pack and the Argyrol spray (20 per cent solution) have become standard therapy throughout the world. Rhinologists, following the Dowling technique, find the tampon saturated with 10-20 per cent. Argyrol solution, the most effective when used as a local detergent and decongestive for the highly inflamed nasal tissues. The new Argyrol Brand Silver Vitellin tablets in small convenient vials are a great convenience in nose and throat practice. They not only insure accuracy, purity and genuineness, but also save

time, because a fresh, potent solution is thus made available at a moment's notice, in the doctor's surgery, in the operating room and at the bedside.

Argyrol is a unique and original compound; no other silver salt is like it chemically.

ALASIL

Better Salicylate Therapy

WHATEVER be the season of the year, there is a wide sphere of utility for "Alasil," the improved form of salicylate medication.

"Alasil" is a very definite advance on ordinary compounds of salicylic or acetyl-salicylic acid both in therapeutic efficiency and in freedom from the risk of unpleasant gastro-intestinal sequelae. This high tolerability is due to the fact that "Alasil" is composed of calcium acetyl-salicylate—the least irritating of the salicylate compounds—and "Alocol" (Colloidal Hydroxide of Aluminium), a powerful gastric sedative and antacid.

A careful series of experimental tests has shown that "Alasil" is more completely absorbed than ordinary salicylate compounds and that it is practically free from the risk of liberating free salicylic acid in the stomach.

Wide clinical experience anticipated these findings by demonstrating that "Alasil" can be pushed or prolonged to a much greater extent than ordinary salicylate compounds and that it can be given with safety to children, adults, the aged, and patients with finely-balanced digestive capacities. An analgesic, antipyretic, and sedative of established value.

A supply for clinical trial with full descriptive literature sent free on request.

NUTRITIONAL NEEDS IN PREGNANCY

"Those who have followed the interesting experiment carried out in South Wales . . . in which the diet of expectant mothers has been very materially increased in regard to protein and the B group of vitamins among other supplements such as milk, must have been impressed with the results."
(Brit. Med. Journal., Aug 7th, 1937, p 259.)

Marmite is one of the few foodstuffs especially selected by medical experts for distribution to pregnant women in South Wales and other depressed areas, where the experiment referred to above is being conducted.

MARMITE

is an autolysed yeast extract rich in vitamin B_1 and vitamin B_2 complex.

'DETTOL' and Midwifery

The composition and properties of 'Dettol' make it a most suitable antiseptic for use in the conduct of labour. Its properties enable it to be used in really effective strengths on the skin and mucous membranes. It has been shown that when half a teaspoonful of 30% 'Dettol' is rubbed into the hands, allowed to dry and kept free from gross contamination, the skin remains insusceptible to infection by haemolytic streptococci for at least two hours.

'Dettol' has high germicidal efficiency and this is well maintained in the presence of blood, serum, pus and other organic matter. *'Detiol' is obtainable from chemists in 1/- and 3/- bottles; and in larger sizes for medical and hospital use. These prices do not apply in the Irish Free State and Overseas. Samples and full information on request.*

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various *methods, including* Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, and X-ray room, an *Ultra-Violet* Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate, a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At *all the branches of the Hospital* there are *cricket* grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton), who can be seen in London by appointment.

BURGH OF KILMARNOCK.

NEW MATERNITY HOSPITAL.

RESIDENT MEDICAL OFFICER.

Applications are invited for the post of Resident Medical Officer at the new Maternity Hospital, Kilmarnock. Candidates must not exceed 45 years of age, and preference will be given to those possessing a qualification of the College of Obstetricians. The salary will be at the rate of £300 per annum, rising, subject to satisfactory service, by annual increments of £25 to a maximum of £450 per annum, with free board, lodging, and laundry. The person appointed will be on the staff of the Medical Officer of Health, and will require, in addition to the duties of Resident Medical Officer at the Maternity Hospital, to undertake such other duties as may be assigned to him. The appointment, which will be a designated post under the Local Government and Other Officers' Superannuation Act, 1922, will be terminable by three months' notice on either side. The successful applicant will require to undergo a medical examination.

Applications, stating age, experience, and when at liberty to commence work, accompanied by one copy of each of three recent testimonials, enclosed in envelopes endorsed "Resident Medical Officer," must be lodged with the Subscriber by September 28th, 1937.

Council Chambers, Kilmarnock. N. J. CAMPBELL, Town Clerk.

September 9th, 1937.

COUNTY BOROUGH OF BRIGHTON.

BRIGHTON MUNICIPAL HOSPITAL.

THIRD RESIDENT ASSISTANT MEDICAL OFFICER (male).

Applications are invited for the above post at the Brighton Municipal Hospital, which is a General Hospital containing 620 beds.

Salary £300 per annum, with board, residence and laundry provided.

The appointment is a whole-time one, and will be for a period of one year.

Candidates must have held a house physician's appointment at a recognized hospital, and preference will be given to those who, in addition, have had practical experience of anaesthetics and maternity work.

The candidate must be single.

The post is designated under the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination before being appointed to the position.

Particulars and forms of application can be had from the undersigned.

Latest date for receipt of applications September 27th 1937.

September, 1937. JAS. H. ROTHWELL, Town Clerk.

WEST SUFFOLK GENERAL HOSPITAL, BURY ST. EDMUND'S.

(112 Beds.)

One other Resident Medical Officer.

Applicants must be registered Practitioners.

Applications, stating age, experience and nationality, with three copies of three recent testimonials, to be sent to the Secretary. Applications to be in by September 21st, 1937. The vacancy occurs October 1st, 1937.

E. E. HARDWICKE, Secretary.

September 4th, 1937.

POSTGRADUATE COURSE IN VENEREAL DISEASES

LONDON COUNTY COUNCIL (WHITECHAPEL) CLINIC, Turner Street, E.1

(Adjoining the London Hospital.)

A THREE MONTHS' COURSE of INSTRUCTION in MODERN METHODS in the DIAGNOSIS AND TREATMENT OF VENEREAL DISEASES will be given by LIEUT.-COLONEL E. T. BURKE, D.S.O., the Director of the Clinic, during OCTOBER, NOVEMBER and DECEMBER, 1937. Attendance at this Course will qualify, subject to the other conditions in the Regulations of the Ministry of Health, for the Certificate enabling the possessor to hold the post of a Venereal Diseases Officer under the Council of a County or County Borough.

The Course will consist of twenty-five systematic lectures accompanied by lantern demonstrations on Mondays and Thursdays at 2.30 p.m., beginning on October 4th and ending on December 23rd. Every Wednesday at 2.30 p.m. cases will be demonstrated. Those taking the Course will also attend the practice of the Clinic in order to obtain tuition in intravenous injections, etc. During the three months, 130 hours of attendance must be put in.

Those intending to take the Course must send their names to the Director on or before September 29th.

Fee: £10 10s.

HULL CORPORATION HEALTH DEPARTMENT.

ASSISTANT MEDICAL OFFICER OF HEALTH FOR PORT SANITARY WORK.

Applications are invited from duly qualified medical men, under the age of 40 years and of not less than three years' standing in their profession, for the appointment of an ASSISTANT MEDICAL OFFICER OF HEALTH, at a salary of £600 per annum, rising by annual increments of £25 to £700 per annum.

Candidates must hold a registered degree or diploma in State Medicine or Public Health.

The person appointed will be engaged primarily on routine Port Sanitary Work, Medical Inspection of Aliens, Bacteriological Work, and the Control of Infectious Diseases, but may be called upon to do work in any other department of the Public Health Services in accordance with the Corporation's scheme for the interchange of medical staff.

Experience in Port Sanitary Work and Infectious Diseases will be considered important qualifications for the appointment.

The appointment may be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Applications, on forms to be obtained from the undersigned, with copies of not more than three recent testimonials, are returnable not later than noon on Thursday, September 23rd, 1937.

Health Department. NICOLAS GEBBIE, M.D., Guildhall, Hull. Medical Officer of Health.

September, 1937.

LIVERPOOL COUNTY BOROUGH. LOCAL EDUCATION AUTHORITY.

ASSISTANT SCHOOL MEDICAL OFFICERS

Applications are invited for THREE ASSISTANT SCHOOL MEDICAL OFFICERS in the Department of the Medical Officer to the Local Education Authority, at a salary in each case of £500 per annum, rising by annual increments of £25 to £700 per annum.

(Where a successful candidate holds a similar appointment under another Local Education Authority, and receives a salary in excess of the advertised minimum, a commencing salary of not less than the salary which the candidate is receiving under his (or her) existing appointment (not exceeding the maximum under the Liverpool Scale) may be paid.)

Candidates must be Registered Medical Practitioners, and must have had at least three years' experience.

The Officers appointed will be required to reside within the City, and devote whole-time service to the Local Education Authority, under the direction of the Medical Officer to the Local Education Authority, and will not be allowed to undertake any private practice.

The appointments will be subject to the Local Government and Other Officers' Superannuation Act, 1922, and the Standing Orders of the City Council.

Form of application, which may be obtained by forwarding a stamped, addressed foolscap envelope, should be returned, together with copies of three recent testimonials, to the undersigned not later than September 25th, 1937, and endorsed "Assistant School Medical Officer."

The canvassing of Members of the Education Committee or the City Council is strictly prohibited, and will be considered a disqualification.

W. H. BAINES, Town Clerk, and Clerk to the Local Education Authority.

Municipal Buildings, Liverpool, 2

September 17th, 1937.

ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in January, 1938.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years in the first instance, which may be extended to five years at the discretion of the Admiralty.

At the end of three years' service officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000.

At the end of five years' Short Service permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Opportunities are available for officers on the permanent list to specialise, and ample provision is made for Post-Graduate study.

Copies of the regulations for entry and conditions of service, including rates of pay and allowances, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than November 22nd, 1937.

COUNTY BOROUGH OF SMETHWICK.

SENIOR ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER

The Council invite applications from qualified medical men for the combined post of Senior Assistant Medical Officer of Health and Assistant School Medical Officer. The officer will rank next in seniority to the Deputy Medical Officer of Health.

The salary will be at the rate of £680 per annum, rising by £25 per annum to a maximum of £800 per annum. The officer will be required to reside at the Isolation Hospital and a deduction of £150 per annum will be made in respect of board, residence and laundry.

The officer appointed will work under the general supervision and control of the Medical Officer of Health and School Medical Officer, and will be required to render assistance in the general work of the department. The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the selected candidate will be required to pass a medical examination.

Forms of application may be obtained from the Medical Officer of Health, Public Health Department, Hales Lane, Smethwick, to whom application endorsed "Senior Assistant Medical Officer of Health and School Medical Officer," and accompanied by copies of three recent testimonials, must be delivered not later than first post on September 25th, 1937.

Canvassing, directly or indirectly, will disqualify.

Council House, FRANK CHAPMAN,
Smethwick. Town Clerk.
September 6th, 1937.

BOROUGH OF WILLESDEN.

RESIDENT MEDICAL OFFICER

Applications are invited for the post of Resident Medical Officer at the Willesden Municipal (Fever) Hospital. The salary will be at the rate of £250 per annum with board, lodging and laundry, and the appointment is for a period of twelve months. The Hospital admits all the notifiable diseases.

Applications, stating age, qualifications and previous experience, with copies of three recent testimonials, to be sent to the Medical Superintendent, Willesden Municipal Hospital, Brentfield Road, Neasden, N.W.10

E. A. PRATT,
Town Clerk.
September 6th, 1937.

CITY OF MANCHESTER.

MONSALL HOSPITAL FOR INFECTIOUS DISEASES (600 Beds.)

APPOINTMENT OF TWO RESIDENT ASSISTANT MEDICAL OFFICERS.

The Public Health Committee invites applications from registered medical men for the post of Resident Junior Assistant Medical Officer (grade 2) at the Monsall Hospital.

Preference will be given to applicants who have held resident surgical and medical posts in a general hospital, and have taken the diploma in Public Health, or have special experience in bacteriology, and who have had previous experience in fevers.

The salary for the appointments is £250 per annum with board, residence and laundry in addition, subject to the Manchester Corporation conditions of service.

The appointments will be made in the first instance for a period of six months, renewable for a further six months, but not renewable thereafter.

Full information and forms of application may be obtained from the Medical Officer of Health, Sunlight House, Quay Street, Manchester, 3, and applications for the post must be received by him not later than September 25th, 1937.

F. E. WARBRECK HOWELL,
TOWN CLERK.

Town Hall, Manchester, 3.
September 6th, 1937.

CITY OF COVENTRY.

MUNICIPAL GENERAL HOSPITAL.

The Public Health Committee invite applications from duly registered male medical practitioners in connection with two vacancies for ASSISTANT RESIDENT MEDICAL OFFICERS at the above Hospital (324 beds). The Hospital includes medical, surgical, obstetric and children's wards.

Each appointment will be for a period of one year. The salary will be at the rate of £250 per annum for the first six months and at the rate of £300 per annum for the second six months, with board, residence and laundry. The officers appointed will be required to pay to the Corporation any fees received in connection with their official work.

Applications, accompanied by copies of three recent testimonials, must reach the undersigned not later than first post on September 28th, 1937.

The Council House, A. MASSEY,
Coventry. Medical Officer of Health.
September 11th, 1937.

LANCASHIRE COUNTY COUNCIL.
PUBLIC ASSISTANCE COMMITTEE.
LAKE HOSPITAL AND DARNTON HOUSE, ASHTON-UNDER-LYNE, NEAR MANCHESTER.

APPOINTMENT OF JUNIOR RESIDENT MEDICAL OFFICER.

Applications are invited from registered medical practitioners for the appointment of Junior Resident Medical Officer at the above Hospital and Institution, comprising 390 and 525 beds respectively. The Hospital is recognized as a complete Training School for Nurses.

Candidates must be unmarried. Salary at the rate of £225 per annum, together with the usual residential emoluments.

The appointment will, in the first instance, be for a period of six months, the successful applicant being eligible for reappointment for a further period of six months at the end of that period.

Forms of application may be obtained from the County Medical Officer of Health, Public Assistance (Hospital and Medical) Department, County Offices, Preston, to whom all applications, accompanied by copies of not more than two recent testimonials, must be forwarded not later than Wednesday, October 6th, 1937.

County Offices, GEORGE ETHERTON,
Preston. Clerk of the County Council.
September 9th, 1937.

CITY AND COUNTY OF THE CITY OF CHESTER.

CITY HOSPITAL (258 Beds).

Applications are invited for the post of SENIOR RESIDENT MEDICAL OFFICER (Male) at the above Hospital. Applicants must have had experience in a Voluntary Hospital as a House Physician and/or experience as a Resident Medical Officer in a Municipal General Hospital. The person appointed will be responsible, under the direction of the Medical Officer of Health for the City, who is also Medical Superintendent of the Hospital, for the general medical work of the Hospital. The salary attached to the post is £400 per annum, rising by two annual increments of £25 to £450 per annum, with board, residence, and laundry.

Canvassing, either directly or indirectly, will be a disqualification.

Applications, stating age, qualifications, and previous experience, with copies of three recent testimonials, must be received by the Medical Officer of Health, Town Hall, Chester, on or before October 1st, 1937.

Town Hall, Chester. J. H. DICKSON,
September 13th, 1937. Town Clerk.

COUNTY COUNCIL OF MIDDLESEX.

RESIDENT ASSISTANT MEDICAL OFFICERS.

Applications are invited for the appointment of three Resident Assistant Medical Officers, two for duty at West Middlesex County Hospital, Isleworth, and one at Hillingdon County Hospital, Uxbridge. Candidates must be registered medical practitioners who have held resident appointments in a general hospital.

Special experience in surgery is required for the Isleworth appointments. The officer appointed to Hillingdon will act as an anæsthetist.

The officers appointed will work under the direction of the Medical Superintendent, and will devote their whole time to official duties.

Salary £400 per annum, rising by annual increments of £25 to £475 per annum, with board, lodging and laundry, valued at £100 per annum.

The appointments, which do not carry any superannuation rights, are for a period of four years, at the end of which period the officers will leave the Council's service. In a special case the Council may decide to retain an officer on the established staff in which case the salary will be increased to a maximum of £500.

Applications, stating age, qualifications and experience, together with copies of not more than three recent testimonials, must be received by the undersigned not later than October 2nd. Application forms are not provided. Envelopes must be endorsed "Assistant Medical Officer, West Middlesex County Hospital," or "Hillingdon County Hospital," as the case may be. Relationship to any member or officer of the Council must be disclosed in the application.

Canvassing, directly or indirectly, will be a disqualification.

C. W. RADCLIFFE, "Z."
Clerk of the County Council.

Middlesex Guildhall,
Westminster, S.W.1.
September 8th, 1937.

COUNTY COUNCIL OF MIDDLESEX.

ASSISTANT MEDICAL OFFICER.

Applications are invited for the appointment on the permanent staff of an Assistant Medical Officer in the Public Health and School Medical Department. Salary £300 per annum, rising after two years' service by annual increments of £30 to £450, together with out-of-pocket travelling expenses.

Applicants must be duly qualified registered medical practitioners, and should have had special experience of ante-natal work. The possession of a Degree or Diploma in Public Health will be an additional qualification.

The duties of the post are the medical inspection of school children, the supervision of treatment of minor ailments, the carrying out of work under the maternity and child welfare schemes, and such other duties as may be required by the Council.

The officer appointed will devote whole time to the duties of the post and will be subject to medical examination which will be held during the pleasure of the County Medical Officer of Health, and will be terminable by one month's notice on either side.

Applications, stating age, qualifications and experience together with copies of not more than three recent testimonials, must be received by the undersigned not later than October 2nd. Relationship to any member or officer of the Council must be disclosed in the application. Application forms are not provided. Envelopes must be endorsed "Assistant Medical Officer 'Z'."

Canvassing, directly or indirectly, will be a disqualification.

WARNEFORD GENERAL HOSPITAL.
LEAMINGTON SPA.

CASUALTY OFFICER and JUNIOR HOUSE SURGEON (combined post) required. Duties to commence at once. Six months' appointment, renewable. Salary £150 per annum, with board, residence and laundry.

Candidates must be qualified, registered under the Medical Acts and unmarried.

Applications, stating age and experience, together with copies of recent testimonials, should be sent to the undersigned.

EDWARD L. WIRGMAN,
House Governor and Secretary.

COUNTY COUNCIL OF DURHAM

EDUCATION DEPARTMENT.

ASSISTANT OCULIST.

Applications are invited for the post of ASSISTANT SCHOOL OCULIST to the Education Committee. Candidates must be skilled Refractionists and must also have occupied the post of House Surgeon in an eye hospital, or in the eye department of a general hospital for a period of not less than six months. Commencing salary £500 per annum, rising by annual increments of £25 to a maximum of £700 per annum, with travelling expenses in accordance with the County Regulations.

The person appointed will hold an established post under the Local Government and Other Officers' Superannuation Act, 1922, and will be subject to the provisions of that Act. He (she) will be required to devote his (her) whole time to the duties of the office and to reside at a place to be approved by the Education Committee. The appointment will be subject to three calendar months' notice on either side, expiring on the last day of any calendar month.

Canvassing, directly or indirectly, is prohibited and will disqualify.

Forms of application, to be returned not later than Saturday, October 9th, 1937, can be obtained from the Director of Education, Shire Hall, Durham, on receipt of a stamped addressed foolscap envelope.

THOS. B. TILLEY,
Shire Hall, Durham. Director of Education.
September 13th, 1937.

COUNTY BOROUGH OF WEST HAM.

PLAISTOW FEVER HOSPITAL.

Applications are invited for the appointment of a MALE SENIOR RESIDENT MEDICAL OFFICER at the above-mentioned Hospital.

The salary will be at the rate of £350 per annum, rising by annual increments of £25 to a maximum of £450 per annum, with residential allowances. The appointment is a designated post under the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the statutory contributions under the Act will be deducted from the salary. The successful candidate will be required to pass a medical examination.

Candidates must have held a residential appointment in a general hospital, and preference will be given to candidates who have also had residential experience in a fever hospital.

Applications, accompanied by copies of three recent testimonials, must be made on forms obtained from the Deputy Medical Officer of Health, Municipal Health Offices, 88, Romford Road, Stratford, E.15, and returned to the Town Clerk, Town Hall, West Ham, E.15, not later than Monday, September 27th, 1937.

CHARLES E. CRANFIELD,

APPOINTMENTS.—Contd.

THE ROYAL CRIPPLES HOSPITAL, BIRMINGHAM.
(306 Beds and large Out-Patient Department.)

Applications are invited for the post of RESIDENT HOUSE SURGEON (male), vacant immediately. Salary £200 per annum.

The appointment, which is for a period of six months, is renewable on the discretion of the Medical Board, and is terminable by one month's notice on either side.

Candidates must be unmarried and preference will be given to those with previous experience in General and Orthopaedic Hospitals.

Applications, with copies of three recent testimonials, to be sent to the General Secretary, Royal Cripples Hospital, 80, Broad Street, Birmingham.

HOSPITAL OF ST. JOHN & ST. ELIZABETH, 60, Grove End Road, N.W.8.

Applications are invited for the post of RESIDENT HOUSE SURGEON (male). The post is recognized for the degree of M.S. London University. The appointment will be for six months from November 1st, 1937. Salary at the rate of £75 per annum, with full board.

Applications, together with copies of three testimonials, should reach the undersigned on or before Tuesday September 28th.

F. DUDLEY HOBBS, B.A.,
Secretary.

THE INFANTS HOSPITAL, Vincent Square, Westminster.

Applications are invited for the post of PATHOLOGIST. The appointment will be a full-time one. Salary at the rate of £700 per annum.

An Assistant will subsequently be appointed.

Applications, with copies of not more than three testimonials, should reach the undersigned not later than October 8th.

ALFRED J. SMALL,
Secretary.

CITY OF LIVERPOOL.

RESIDENT ASSISTANT MEDICAL OFFICERS.
Broadgreen Sanatorium (353 Beds) and Fazakerley Sanatorium (265 Beds).

Applications are invited for the above appointments for a period of one year, at a salary of £250 per annum, together with usual residential allowances.

Candidates must possess a registered medical and surgical qualification, and it is desirable that they should have held previous appointments in a teaching Hospital.

Canvassing will be deemed a disqualification.

Applications to be made on forms obtainable from the Medical Officer of Health, Municipal Annexe, Dale Street, Liverpool, to be endorsed "Resident Assistant Medical Officer," and returned to the undersigned so as to be received not later than Thursday, September 30th.

W. H. BAINES,
Town Clerk.
Municipal Buildings,
Dale Street, Liverpool, 2.
September, 1937.

HOSPITAL OF ST. CROSS, RUGBY.
(120 Beds.)

Applications are invited for the post of ONE MALE RESIDENT MEDICAL OFFICER (three R.M.O.'s).

Salary to commence at the rate of £100 per annum for the first three months, £125 per annum for second three months, and at the rate of £150 per annum for subsequent months. Full board, washing, etc., provided.

Six months' appointment and eligible on completion of service for further extension of six months.

Candidates must be prepared to commence duties on Monday, October 4th, 1937.

The practice of the Hospital offers excellent opportunities for wide experience.

Certificates and other fees shared by R.M.O.'s.

Applications, stating age, nationality, and full details, with copies of three recent testimonials, to be sent to the undersigned.

(Signed) W. COCKBURN,
Superintendent and Secretary.

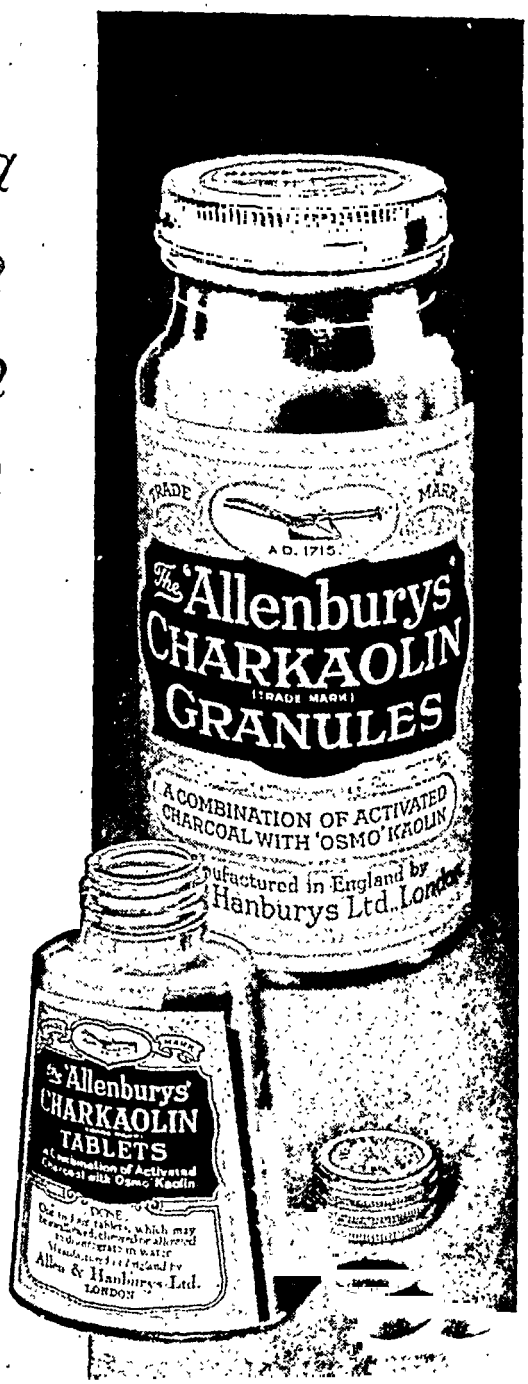
[illegible] is practically unopposed and country, was [illegible] 40 years ago and now for disposal owing to [illegible] three years have been about £540 p.a., and there is stated to be good scope for increase as practice has been neglected. Panel of about 600 patients. Suitable house available on rental at £30 p.a., with 2 reception and 4 bedrooms, garden and garage. Premium 1½ years' purchase.
8. CROYDON AREA.—Rapidly increasing PRACTICE, established 5 years ago, for disposal as vendor [illegible] to be: 1935, £1,127; 1936 [illegible] patients. Fees 1/6 to 3/- [illegible] available. Fees practically [illegible] 2 years' purchase.
9. EAST LONDON.—Old-established PRACTICE producing about £1,800 p.a. Panel of nearly 2,600 patients. Fees 2/- to 3/-. Visits from 3/-. Midwifery, 3 to 5 guineas, about 20/30 cases yearly. Very good house on rental at £120 p.a. Accommodation consists of surgery, waiting room, 2 reception and 4 bedrooms, 2 maids' rooms and bathroom. Garage. Premium £3,600.
10. LONDON.—Outlying Northern Suburb.—PARTNERSHIP—A one-third share is available in a rapidly expanding Practice. Receipts for past three years are approximately £1,924-£2,900 and £3,550. Panel of 2,354 patients. Fees 2/6 and 3/6—visits 3/6 upwards. Midwifery about 40/50 cases per annum, minimum 4½ guineas. Considerable scope for further increase. Ingoing partner must be well experienced and have held Hospital appointments, be interested in medicine and children, and, in addition, be a good anaesthetist. Short preliminary assistantship.
11. LANCS.—High-class Seaside and Residential Town.—Easily worked old-established PRACTICE for sale. Gross cash receipts about £1,100 p.a., including a panel of about 325 patients. Fees 3/6 to 10/6. Visits 5/- to 21/-. Midwifery about 12 cases p.a. Minimum 5 guineas rising to 15 guineas. Mostly non-dispensing. Low expenses. Suitable house available with consulting and waiting rooms, 2 reception, 3 bedrooms and a maid's room and box room. Large garden and garage. Leasehold for sale or would be rented. Premium 1½ years' purchase. There is stated to be good scope for increase for an energetic man.
12. SUSSEX.—ATTRACTIVE COUNTRY DISTRICT NEAR SEA.—PARTNERSHIP.—A one-fourth share is offered (after a preliminary assistantship) in an old-established and expanding Practice. Gross cash receipts for 1936 were about £3,300 and for the past 8½ months approximately £2,700. Panel of 1,300 patients. Appointments worth over £300 p.a. Maisonette available or Senior partner might build new house. Premium 2 years' purchase.
13. OPHTHALMIC PRACTICE for sale in a capital Australian City.—Gross cash receipts approximately [illegible] consulting rooms can be rented at £180 p.a.
14. PHYSIO-THERAPEUTIC [illegible] X-ray work in large town. ONE HALF [illegible] ver £2,000 p.a.
15. WEST END PRACTICE.—Death Vacancy.—Skins—Genito-Urinary—V.D., Electro-Therapy, etc. Gross cash receipts for past 12 months about £1,515. Fees 2 and 3 guineas. Suitable accommodation available. Premium by arrangement.
16. NORTH-WEST COAST.—Well-established PRACTICE, with seaside town and country work, producing £1,299, including panel and appointments worth about £400 p.a. Suitable house with 3 bedrooms, etc., garden, garage. Rent £50 p.a. Sport of all kinds. Premium only £1,250 for quick sale.
17. NORTH-EAST COAST.—Well-established non-panel PRACTICE, averaging about £900 p.a., but capable of extension as considerable building is in progress. Very good house, with 6 bedrooms, etc. Price £1,500. Premium 1½ years' purchase.
18. SOUTH COAST.—PARTNERSHIP.—A ONE-HALF SHARE in good middle and upper-class practice producing about £2,550 p.a. Panel of 1,300. Fees 3/6 to 21/-. Suitable house can be rented at £65 p.a. Easily worked, and scope for increase. Premium 2 years' purchase.
19. DEVON COUNTRY.—Old-established PRACTICE producing about £800 p.a. including about £310 from panel of 428 patients. Freehold house for disposal containing 2 reception rooms, lounge hall, 6 bedrooms, waiting room, consulting room, etc., 1½ acres of garden, garage for 2 cars and stabling. Freehold £2,600. Premium £1,200.
20. LANCS.—Suburb of large town. PRACTICE producing about £800 p.a. with panel of 467 patients. Suitable house on rental at £90 p.a. inclusive. Stated to be scope for increase. Premium £1,100.
21. LONDON, S.E. 11.—Old-established working class PRACTICE producing approximately £500 p.a. Panel of about 500 patients. Can be worked as lock-up. Premium 1 year's purchase or any reasonable offer accepted.
22. YORKS.—LARGE TOWN.—Well-established better working-class PRACTICE. Receipts for last 12 months about £1,176 with Panel of 1,150 patients approximately. Fees, minimum 2/6 with visits from 3/6 to 7/6. Freehold house for disposal at £900 containing 3 bedrooms, 2 living rooms, surgery, waiting room, etc. Vendor wishes to specialise.
23. EASTERN COUNTY AND MARKET TOWN.—HALF-SHARE PARTNERSHIP in Practice established some 100 years owing to retiral of junior partner. Average cash receipts over £2,400 p.a., of which over £700 comes from Panel and P.A.C. Suitable house available on rental. Ingoing partner should not be more than 30, preferably have a degree and some hospital experience.
24. ASSISTANTSHIP—with a view to a PARTNERSHIP SHARE to produce about £1,100 p.a., in a well-established Practice. Ingoing man must be young, have had considerable hospital experience, and preferably held an Ophthalmic H.S. He should be married or engaged, and a Protestant. Will applicants please give full details of experience, etc.
25. DEVON, SOUTH COAST.—A well-established good-class entirely private PRACTICE producing for the past 12 months about £1,000. Panel could be had if desired. Fees 2/6, 3/6, 5/- and 7/6, with a few visits up to 21/-. Non-dispensing. Suitable house containing consulting room, 2 reception rooms, 6 bedrooms, for sale. Freehold £1,400. Partnership introduction. Would be suitable for ex-I.M.S. or similar.
26. DEVELOPING NORTHERN SUBURB.—A 3/8TH SHARE is offered in a well-established and growing Practice. Receipts for 12 months to 1/4/37 amounted to about £5,200, including about £80 from appointments and a [illegible]
27. [illegible] ished for [illegible] to about [illegible] and 3/6. [illegible] Suitable house with good accommodation and separate surgery available on lease at £60 p.a. Premium £1,100, plus good debts, drugs and surgery equipment at valuation. Vendor giving up owing to ill-health.
28. LONDON, E.2.—Lock-up PRACTICE established 80 years for disposal. Income about £800-£900 p.a., with Panel of about 1,150 patients. Fees 2/6 and 3/6. Visits from 3/6. Suitable accommodation available consisting [illegible] ing room, the remainder being sub-let for [illegible] Premium 2 years' purchase to include [illegible] etc.
29. [illegible] hours 10-1 and 5.30-6.30, producing about £1,000 p.a., including £200 from Panel and appointments. Suitable accommodation available.
30. BAYSWATER.—PRACTICE, established some 65 years for disposal. Gross receipts about £1,440 p.a., with 1,000 Panel patients. Suitable house on lease at £130 p.a. Premium 2 years' purchase.
31. SURGICAL OPENING.—WITHIN 50 MILES OF LONDON.—A £1,000 share is offered to a FIFTH PARTNER in an old-established Practice. The patients comprise all classes and there is little visiting done under 10/6. Ingoing partner would do all surgery, but must be prepared to do ordinary G.P. as well. Choice of houses. Applicants must be 28-40, preferably hold a degree and must have their English Fellowship. Premium 2 years' purchase.
32. LONDON, S.W.—Old-established PRACTICE producing £1,500 p.a., with panel of 1,266 patients for disposal. Appointment and small club bring in about £85 p.a. House available contains Professional accommodation, reception room and 3 bedrooms and maids' room, bathroom. For sale or might be rented. Premium £3,000.
33. NORTH-WEST COAST.—SEASIDE TOWN.—CONSULTING PRACTICE FOR A PHYSICIAN.—Established by vendor (who now wishes to come to London) 4 years ago. Receipts for last year stated to be £1,320 Minimum fee 2 gns. Suitable rooms available at inclusive rental of £64 p.a. Purchaser can choose his own residence and should hold the M.D. or M.R.C.P. Premium 1½ years' purchase on actual receipts for first year.
34. HAMPSHIRE.—COUNTRY PRACTICE.—Old-established PRACTICE held by vendor for past 7 years. Gross cash receipts stated to average £740 p.a. Panel of 472. Appointments worth about £130 p.a. Fees 3/6 upwards. Pleasant house containing 2 reception, 5 bedrooms, etc., Professional accommodation. Good garden and garage. Rent £55 p.a. Prem. £1,250.
35. SUSSEX.—VILLAGE PRACTICE NEAR COAST.—Well-established PRACTICE producing about £800 p.a., and capable of increase, attractively situated within five miles of favourite seaside resort. Very nice house, with ¾ acre of garden, in excellent repair. Price for Practice and house, £3,100 or house might be rented for a short period.
36. EASTERN COUNTIES.—Mixed-class PRACTICE in pleasant agricultural district producing for last twelve months over £1,300 p.a. Fees 3/6 to 21/-. Nice house in good position with 2 reception, 4 bedrooms, dressing room, etc. Separate professional accommodation. Modern conveniences. Garden, garage. Price for freehold £1,300. Sport of all kinds and schools within reach.

The Agency has made arrangements for special facilities, on very favourable terms, to be afforded to approved purchasers for the advance of part of the premium for any suitable practice or partnership. Full details on application.

Intestinal Toxæmia with Hypertension Gastric Fermentation and Distension

CHARKAOLIN adsorbs toxins and gases in the stomach and intestines. An index of its adsorptive activity is its complete deodorisation of the intestinal contents.

CHARKAOLIN has given remarkable results in some cases of *hypertension with intestinal* auto-intoxication.



CHARKAOLIN is the original preparation of activated charcoal with Osmo Kaolin.

'Elastoplast' in the treatment of large and deep-seated Varicose Ulcers

In the case of a large or cavitated ulcer, greater support is afforded to the lesion by the use of Paragon Sponge Rubber in conjunction with the 'Elastoplast' bandage. Two strips of the 'Elastoplast' bandage, 6 in. long are cut and laid one on each side of the leg from the malleolus upwards. Then a piece of the sponge rubber of suitable size is placed over the ulcer, completely surrounding it for several inches, before the 'Elastoplast' Bandage is applied in the usual manner, from the toes upwards, as tightly as possible. The sponge rubber, besides giving extra support, prevents the bandage from cutting into the ulcer and the surrounding weak tissue, and also promotes quicker healing.

A copy of "Elastoplast Technique," giving particulars of this and many other uses of the 'Elastoplast' bandage, will be sent on request to the address below.

SPECIAL NUMBER OF

October

ADVANCES IN DIAGNOSIS

A review of recent advances in the diagnosis and treatment of disease by a team of experts means, in fact, an up-to-date supplementary textbook of medicine and all its specialties in handy form. Practitioners who study this Special Number will find important advances judiciously considered. The value of the latest radiological methods, the use of antistreptococcal chemical preparations, benzedrine, sex hormones, and the newest insulin combinations are among the important subjects dealt with.

The article in the new series on Diet in Health and Disease deals in this issue with diet in infectious fevers.

THE GREATEST WORK IN THE HISTORY OF MEDICAL BOOKS

POST-GRADUATE SURGERY

(INCLUDING PRE- AND POST-OPERATIVE TREATMENT)

Edited by **RODNEY MAINGOT**, *F.R.C.S.(Eng.) in collaboration with 60 eminent and authoritative experts.*

NOW COMPLETE IN 3 VOLUMES

Truly a notable contribution to British Medical Science, as it gives information which cannot be found in any other text-book hitherto published. It will prove of undoubted help to Post-Graduates, Hospital R.O.'s, Fellowship Candidates, M.O.'s of the Services and General Practitioners.

Every doctor should read this novel

SIDNEY FAIRWAY'S

THANKS TO DOCTOR MOLLY

5th Impression

Sidney Fairway's two famous novels, *A Cuckoo in Harley Street* (9th imp.) and *The Doctor's Defence* (9th imp.), won immediate recognition and caused much controversy both among doctors and the general public. In his latest novel, a very human story of a General Practitioner, he administers "a tonic and a corrective." We prophesy a big success for *Thanks to Doctor Molly.* 7/6

"USE A TYPEWRITER MADE IN THE UNITED KINGDOM"

THE "DOCTORS' SHIRT" *which has detachable sleeves!*

Here is a most useful shirt which for many years we have supplied to the medical profession. With detachable sleeves just above the elbow, it fastens with four small buttons which are adjusted with a minimum of trouble. The "Doctors' Shirt" possesses also these additional points of interest.

1. It keeps the cuffs smooth instead of being creased up by the process of rolling.
2. There is no fear of them coming down at an inopportune moment.
3. There is no muster of material about the biceps to interfere with the action of the arm.

The "Doctors' Shirt" is made in white poplin 10/6, Collars 1/3 extra. Extra half sleeves sold separately. Also other fabrics striped or plain. For prices, patterns, and self-measurement form send to Dept. B.M.J.

DESOUTTER

CASE RECORDS

Case No. H2029. 1934

Mrs. B., a patient with a left Syme's amputation, came to see us in 1934 with an appliance that she had been wearing for two years which was ugly, heavy and ill-fitting, and causing her great discomfort. As a result of incorrect alignment the steel supports had caused pressure sores to develop at the inner side of the knee and outer end of the stump.

The end bearing, which should be the great asset of Syme's amputation, was taking practically no weight, by far the greater part of the weight being taken on a thigh corset with a bearing on the ischial tuberosity. Yet, in spite of this, the end pad of the stump was already showing signs of loosening due to the outward lateral movement which took place at every step (see Figure 1). If such end results are obtained, it is small wonder that many surgeons may regard Syme's amputation as unsatisfactory. In point of fact a Syme's can be as satisfactory an amputation as any other, when correctly fitted, as the case in question shows.

A plaster cast of the stump was taken, the positive copy of which was suitably modified to make use of the weight bearing points under the knee, and to ensure that the end bearing pad could expand without friction whilst taking a full share of weight. A leather glove was then moulded to the cast (see Figure 2) and encased in a light metal shin with a thin stainless steel cup forming the end bearing, giving great strength combined with lightness and a smooth outline, the mechanism for the ankle movement being a self-contained unit under the end bearing. Owing to the fact that the lower end of a Syme's amputation is much larger than the leg above it, it is only necessary to allow the lower end of the leather glove to open; the fastenings to the metal shin are quick and simple and so firm that once the limb is on it cannot be pulled off. The result is a comfortable light limb of neat appearance (this of no small importance to a woman), taking the weight on the end bearing and below the knee (see Figure 3).

'VARIBAN' ELASTIC PLASTER BANDAGE

"VARIBAN" BANDAGE constitutes a marked advance on the older methods of treating chronic ulceration of the leg. It is made from a specially woven selvedge material possessing highly elastic properties, and is impregnated with an antiseptic zinc oxide paste.

"VARIBAN" is self-adhesive and combines the principles of firm, equable pressure and support to the swollen leg, with the benefit of an occlusive dressing under which the ulcer is protected and is stimulated to healthy repair.

In promoting proper circulation, "VARIBAN" steadily reduces oedema. It provides protection to the granulations of the healing ulcer. In the majority of cases it is found that pain is either eliminated or greatly relieved from the first application. The necessity for ointments, lotions, etc., is obviated, while "VARIBAN" provides an ambulatory treatment which allows of full activity of the limbs with better results than those following rest in bed alone.

AN EXACT REPRODUCTION OF THE NATURAL LINE OF THE BUST

THE SALTAIR ARTIFICIAL BREAST
AND BRASSIERE

● The restoration of the natural line of the bust after operation is a problem that has been effectively solved by the introduction of THE SALTAIR ARTIFICIAL BREAST. This surgical fitting is designed so that it cannot slip out of position. It is very resilient, has a beautifully smooth surface, and weighs only two ounces. It retains its shape when wet and is easily dried, so that bathing can be enjoyed with confidence. Wearing THE SALTAIR ARTIFICIAL BREAST, the patient is freed from embarrassment and is able to resume her normal life and those social pleasures which are so essential to her physical and mental well-being.

● The photograph shows patient wearing THE SALTAIR ARTIFICIAL BREAST with the special Brassiere. Pad can be supplied separately and is easily sewn into patient's own foundation garment if preferred. The breast is available in three sizes, which can be sent on approval. Full details sent post free to Medical Men upon request.

'CYSTAZOL'

A POWERFUL URINARY ANTISEPTIC

'Cystazol' is a combination of Hexamine with Sodium Benzoate: its action depends on the liberation of formaldehyde from the decomposition of the hexamine that takes place in the urine which has been rendered acid by the sodium benzoate moiety.

'Cystazol' is employed with advantage in cystitis, bacilluria of all types, pellagra, gonorrhœa and septic conditions of the urinary tract generally.

COMPRESSED TABLETS of 'Cystazol'

Supplied in bottles of 20, 40, 80, 160 and 500 (10 grain) tablets, at 1/6, 2/6, 4/6, 8/6 and 20/-

EFFERVESCENT GRANULES of 'Cystazol'

Supplied in bottles at 2/6 and 4/6.

Manfield House, Strand, London, W.C.2.

TESTED:

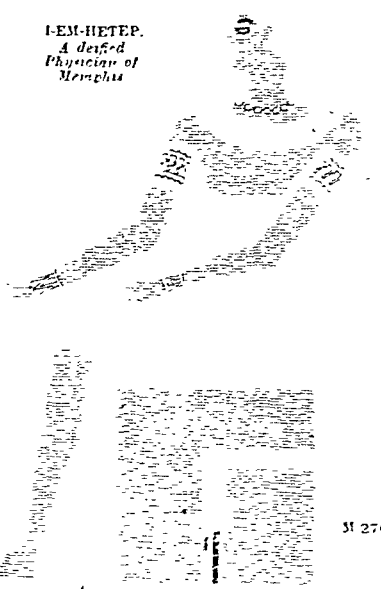
In the three laboratories devoted exclusively to the preparation of intravenous solutions, not a single item is left to chance. Each mixture of solution must prove itself by passing exhaustive tests and inspections. These tests include a more than adequate biological check, complete bacterial, yeast and malt tests at incubator and room temperatures, chemical assay, checking of the *p*H and visual inspection with special equipment. This constant vigilance is your protection and ensures absolute freedom from all reactions.

Vacoliter

ONE LITRE (1000 C.C.) PACKED IN METAL

OVALTINE

IN PREGNANCY



THE physiological drain of calcium, phosphorus, vitamins and other important food elements calls for replacement during pregnancy. Composed of milk, eggs and malt, 'Ovaltine' supplies these essentials in a delightful form which does not overtax the unstable maternal digestion A cup of 'Ovaltine' on arising, during the early months, is often effective in controlling sickness and has a food value greater than three eggs.

IN LACTATION

To maintain lactation to the eighth month is an ideal not often realized under modern conditions of life. Ample evidence is available to show that 'Ovaltine' has a definite action in increasing the flow and enriching the quality of the milk. It has, moreover, a beneficial effect on the health of mother and child. The flavour is so agreeable that it can be taken for prolonged periods without any distaste arising.

Why Lactogen so adequately replaces Breast Milk

where natural Feeding is deficient or impossible

Scientifically and in actual practice, Lactogen resembles Baby's natural food as closely as is possible. Both the proportions of its food elements and its physiological character are practically identical.

The homogenisation process reduces the fat globules to a size even smaller than those of breast milk. The curd is light, flakey and easily digested. The vitamins remain practically unaltered, and the mineral salts are presented in an assimilable form.

That is why babies who are deprived of their natural food thrive so well on Lactogen.

Strong, Healthy Babies prove Lactogen next best to natural food

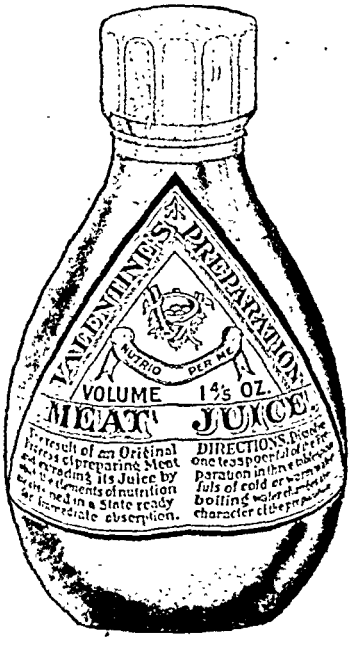
Modern Iron Therapy



Iron 'Jelloids' are an elegant and reliable means of administering the protocarbonate of iron. The preparation has none of the disadvantages of Pil. Blaud. The iron content remains fresh and unoxidized indefinitely, and injury to the teeth is avoided.

The 'Jelloids' are highly effective in the treatment of achlorhydric anaemia and indeed in all the simple anaemias in which massive iron therapy is indicated.

Iron Jelloids

You are cordially invited to apply for samples for clinical test.

IODATOL, 40 PER CENT.

For use in X-Ray Diagnosis

The injection of iodised vegetable oils as a means of conducting explorations of various delicate organs and cavities of the body, for which purpose both barium and bismuth preparations are unsuitable, has now become routine. The method is particularly suitable for use in the examinations of the bronchi and the uterus.

In the Addendum 1936 to the B.P. 1932 the specification for iodised oil (Oleum Iodisatum) is an iodine addition product of poppy-seed oil containing 39 to 41 per cent. of combined iodine. It is a pale yellow, viscous, oily liquid, and is opaque to X-rays. Iodatol, 40 per cent., the original British-made iodised oil, conforms with this specification. Iodatol, 40 per cent., is available in bottles of 20 c.c. and 30 c.c. from the principal pharmacists.

Practical Applications of the

KAYLENE-OL

Treatment

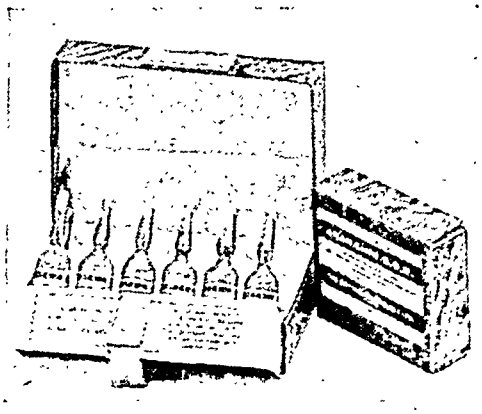
CHRONIC COLITIS

(Simple Mucous, Muco-Membranous, Post-Dysenteric).

(Kaylene Brand of Colloidal Kaolin with highly viscous liquid paraffin)

Alternating intervals of constipation and diarrhoea often occur in cases of colitis. Kaylene-ol is applicable in either phase. Its soothing and adsorptive actions combat the irritative diarrhoea, and its softening and lubricating actions counteract constipation during the intervals.

DOSE—KAYLENE-OL: 1 or 2 dessertspoonsful three times a day, half hour before meals, or in mild cases half hour before breakfast and at bedtime.



Kaylene-ol c Phenolphthalein (0.5 per cent.) is taken when constipation is particularly troublesome. Dosage as for Kaylene-ol.

Samples and Literature from the sole manufacturers:

KAYLENE LIMITED, WATERLOO ROAD, LONDON, N.W.2.

ANAHÆMIN B.D.H.

In the treatment of pernicious anæmia

The following report furnishes a record of the remarkable improvement effected in the condition of a pernicious anæmia patient as a result of four injections of Anahæmin B.D.H.

Blood count 720,000. Patient *in extremis*, blood transfusion impossible on account of condition of heart. Injection of 2 c.c. anahæmin followed by second injection of 2 c.c. on third day. On fifth day reticulocytes were 46%. Blood count rose steadily. Doses of anahæmin 1 c.c. on tenth day after second dose anahæmin, and again ten days later 1 c.c. Blood count in under three weeks —2,400,000.

An/S/30

Convalescence

In convalescence a tonic is required that will co-operate with, and augment, the natural recuperative powers of the body, rather than one which will have only an immediate stimulating effect. In the latter case there is always the danger of disappointment, due to an artificial improvement that the natural powers are unable to stabilise.

Medical evidence extending over many years has established the value of Sanatogen in promoting convalescence. In "The Elements of Pharmacy, Materia Medica and Therapeutics", Sir William Whitla writes:—

> "... *The interesting and valuable researches conducted by Tunnicliffe and Beddoes upon metabolism, in which Sanatogen was experimented with, establish the fact that its organic phosphorus is almost entirely assimilated when the food is administered in the amount necessary for the needs of the body. When given in addition to other food, the amount of nitrogen and phosphorus retained in the organism is increased; the tissue metabolism is more complete, the constituents of the ordinary food being more thoroughly utilised; appetite is increased and the body weight augmented.*"

Similarly gratifying observations are constantly being notified, and, as Sanatogen is entirely free from fats, sugars and carbohydrates, it can safely be prescribed in all types of cases. It is rapidly and easily digested and assimilated, even in cases exhibiting severe gastric inflammation, and for this reason it is a valuable addition to enemata. It can be added to any non-acid beverage or food, and, consequently, monotony in its administration can always be avoided.

ACRIFLAVINE 'B.D.'

The antiseptic of universal application

In Surgery

Acriflavine 'B.D.' provides an effective general bactericide and antiseptic for use in surgery; it is particularly valuable in ophthalmic work by reason of the fact that its solutions of a strength sufficient to be actively antiseptic are non-irritating; indeed, for this purpose it has been reported that '. . . *there is nothing to touch it.*'

In Medicine

Acriflavine 'B.D.' is unequalled in its value in the irrigation treatment of gonorrhœa, whilst in such local septic conditions as eczema, impetigo, pediculosis, pemphigus neonatorum and ulcus molle, also in oral sepsis, its application produces remarkably beneficial results. More recently, considerable success has followed the intravenous injection of solutions of a specially-purified Acriflavine 'B.D.' in such internal infections as meningococcal septicæmia.

THE BRITISH DRUG HOUSES LTD. LONDON N.1

F1/S/43

"The Vitamin B_1 activity is assured

by biological assay of *every day's output*"

So far as is known, there is only one food product for which such a claim, involving no fewer than 250 biological assays for Vitamin B_1 per annum, is or can be made.

Unnecessary? Consider this:

"*Unselected yeasts may vary tenfold in their vitamin B content*"—(*J. Nutrition*, 3, 257)

"*Unselected wheat germs may vary fivefold in their vitamin B_1 content*"—(*J. Hygiene*, 37, 303)

Statements as to the Vitamin B_1 potency of foods, etc., couched in general terms, are unacceptable for therapeutic purposes unless supported by (1) an assay of each lot manufactured (2) a guarantee that the potency will not diminish with the passage of time.

How then can the physician make sure that his patient receives, in a natural form, any desired amount of vitamin B? Only by prescribing Bemax.

BEMAX

A unique natural source of accessory nutritional factors.

Vitamin B_1 — 400 International Units per ounce.

Vitamin B_2 — Flavin present.

Vitamin B_6 — (Anti-dermatitis) One of the richest sources.

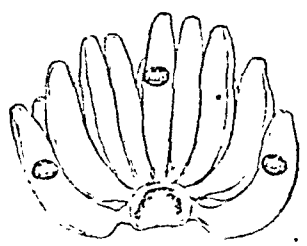
Vitamin A—280 International Units (as Carotene).

Vitamin E—the richest natural source;

Phosphorus — 330 mg. per ounce;

Magnesium — 99 mg. per ounce;

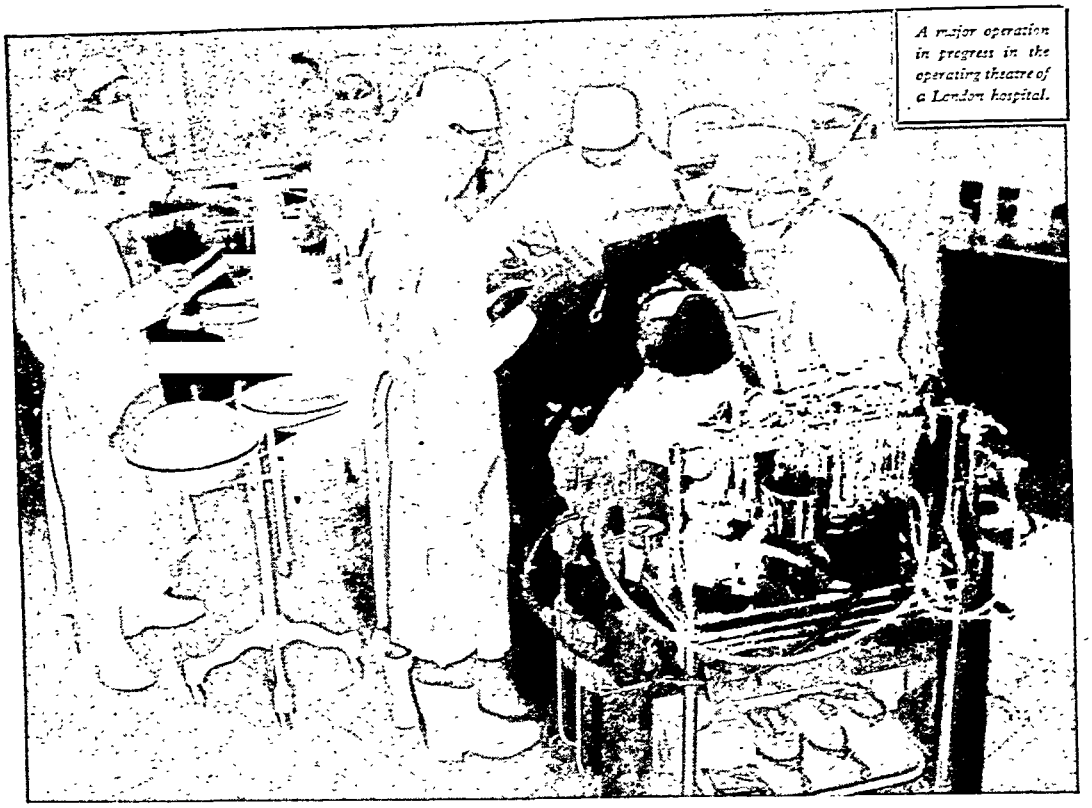
Iron—3 mg. per ounce, and Copper =0.45 mg. per ounce.



THE BEMAX LABORATORIES, (Dept. B45), Upper Mall, London, W.6

THE THERAPEUTIC VALUE OF THE BANANA

III. Coeliac Disease



This nutritional disturbance of early childhood has been found by *Haas* to give way very satisfactorily under treatment with bananas. The carbohydrates of the banana are tolerated perfectly, and combined with sour milk give a diet of high calorific value. The maximum number of bananas used in any one case was sixteen daily for a child of twenty-six months.

The *Haas* treatment is now being extensively used in European children's hospitals with excellent results. The method of administration is usually to rub fully ripe bananas through a sieve, and beat to a cream pulp with milk or other suitable liquid.

N.B. In the fully ripe banana the starch content is reduced to about 3 per cent, having been changed into soluble sugars. A banana is ripe when all green has disappeared from the skin and brown spots have formed upon the yellow surface.

ISSUED BY ELDERS & FYFFES LTD., 31-32 BOW STREET, LONDON, W.C.2

A major operation in progress in the operating theatre of a London hospital.

THE DANGER OF INFECTION

It is not only in the operating theatre that the value of antiseptic protection is to-day recognised. Men and women in everyday life are learning the importance of germ-free cleanliness. More careful attention to hygiene is resulting in better standards of health.

Of course, it is not possible in everyday hygiene for ordinary people to take such elaborate precautions against infection as those taken by the surgeon before an operation. Nevertheless, protective measures against the daily risks of infection are obviously needed, and it is generally accepted that the simplest and probably the most effective protection is that given by washing exposed parts of the body, such as the hands and face, regularly with a reliable antiseptic soap.

Wright's Coal Tar Soap has enjoyed the confidence of the medical profession for health protection for over 70 years. It has substantial antiseptic and anti-pruritic qualities, and is made from the costliest materials obtainable. It is the only soap in the world to contain 'liquor carbonis detergens' (Wright's), the valuable skin therapeutic recommended by leading dermatologists. An investigation by the Institute of Industrial Psychology reveals that more doctors themselves use Wright's than any other brand of toilet soap. You are safe in recommending Wright's to your patients—and in using it in your own practice.

GAS GANGRENE ANTITOXIN POLYVALENT

GLOBULIN Lederle MODIFIED

GAS GANGRENE in humans is believed to be caused by one or more of five pathogenic anaerobic bacteria:—Vibrion septique, B. perfringens, B. oedematiens (Novyi), B. histolyticus, and B. sordelli.

Each of these gas gangrene anaerobes produces a specific infection in that they are toxicogenically unrelated. B. perfringens is the most important causative agent, but only because it is the most common cause of gangrene infection.

The success of serum treatment is dependent upon adequate dosage of antitoxin specific for the particular organism causing the infection, and, of equal importance, its *early use*. Prompt identification of the species of the infecting anaerobic bacteria is usually not possible; therefore, it is recommended that each case of gas gangrene be treated with a mixture of the antitoxins corresponding to the toxins of the commonest causative bacteria.

"GAS GANGRENE ANTITOXIN POLYVALENT LEDERLE" is supplied in vials containing mixed antitoxins in therapeutic doses as follows:—

10,000 units B. perfringens Antitoxin.
10,000 units Vibrion Septique Antitoxin.
2,500 units B. histolyticus Antitoxin.
1,000 units B. oedematiens Antitoxin.
200 units B. sordellii Antitoxin.

This combination of antitoxins is specific for all the toxin-producing, spore-forming anaerobes now credited with causing gas gangrene in man.

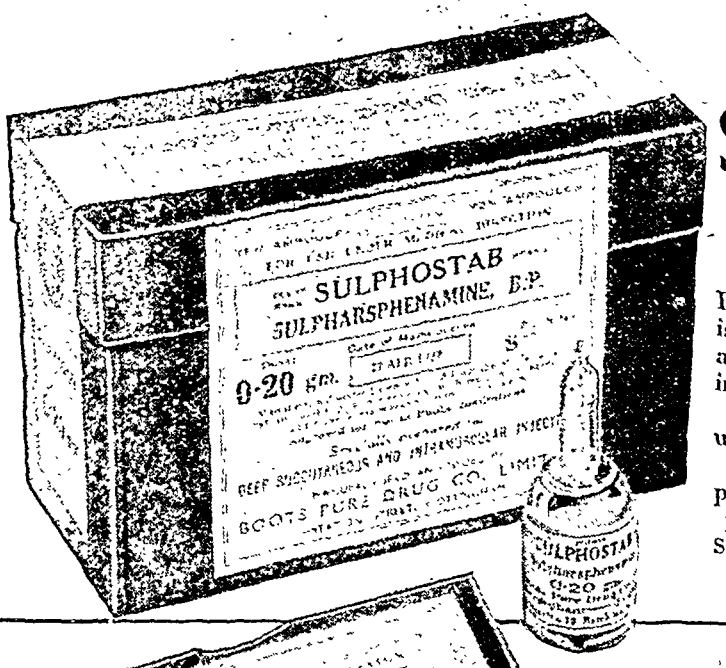
Initial Daily Dose
Two Tablets

Laxatives, it is well known nowadays, must have two essential characteristics.

1. They must be biological, i.e., they must accord with and imitate in their action the natural physiological processes of the intestine.
2. They must be capable of educating the intestine, so that the habit of a laxative is not formed and the intestine can function unaided when bowel adjustment is attained.



Taxol has both these advantages.

Taxol has not the violent irritant action of many laxatives and purgatives, but stimulates the intestine by processes which resemble those of nature. The intestinal gland which is an important part of its composition acts on the intestine by reinforcing the deficient function which has culminated in constipation. This stimulating action is gentle, and does not force the weakened intestine to efforts beyond its power, which would culminate in aggravation of the constipation.

Taxol is not habit-forming. It re-educates the intestine to resumption of normal function unaided, thanks to the biological nature of its action. It contains no irritant drug of violent and artificial action to which the intestine can become accustomed. On the contrary, many stubborn cases of constipation, after a course of TAXOL, revert to normal and regular peristalsis.

MEDISOAPS

(Midgley)

A Comprehensive Series of Medicated Soaps to 49 approved formulae

The variety of the formulae for Medisoaps enables the physician to select a treatment adapted to the particular needs of each case.

Medisoap therapy is in line with the modern call for milder methods in the treatment of skin disease by topical application. In addition, the absence of grease renders Medisoaps acceptable to patients who object to the unsightliness of ointments.

The following Medisoaps are extensively prescribed:—

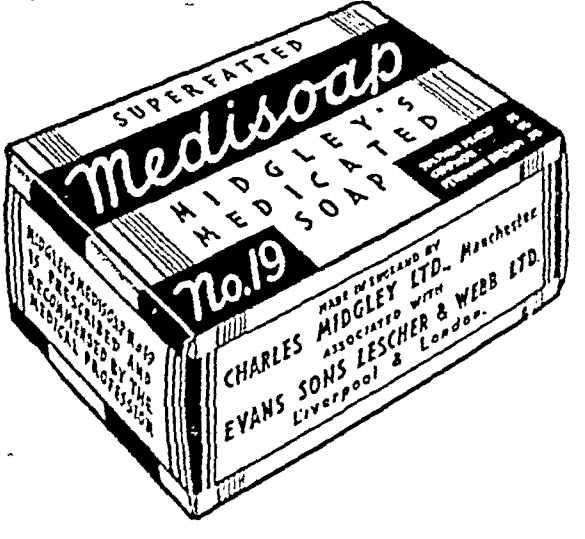
MEDISOAP No. 19

Presents sulphur in a form which is active and non-irritating.
For **Acne, Psoriasis. Scabies, etc.**

Formula:—Sulphur Præcip. P.B. ... 5%
Camphora 5%
Balsam Peru 3%

MEDISOAP No. 18

Specially useful in **Acne Vulgaris.**



Formula:—Sulphur Præcip. ... 10%
Betanaphthol 2½%
Medisoap Pure Base ... 87½%

MEDISOAP No. 10

A cleanly and effective method of applying Ichthammol.

Formula:—Ichthammol 10%
Medisoap Pure Base ... 90%

A Brochure (with a convenient clinical index) giving the full formulæ will be gladly sent on application.

Medisoaps are made by Charles Midgley Ltd., Manchester,
and distributed by

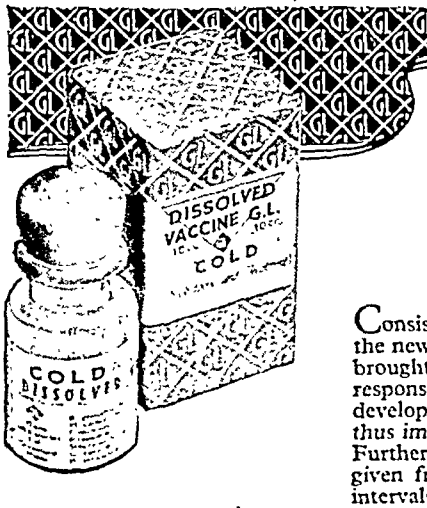
SUPREME QUALITY IS BURROUGHS WELLCOME QUALITY

A BARRIER AGAINST WINTER

OSTOMALT provides protectives as well as calories. The vitamins of Ostomalt perfect the bodily machine; the malt extract feeds it. For young and growing children and for debilitated convalescents, Ostomalt is a protective and rehabilitating nutrient. Besides its nourishing content of malt extract and its natural complement of vitamin B, Ostomalt contains special additions of vitamins A, C, and D. These basic vitamins ensure the orderly growth of healthy tissues, and provide the best defence against disease and relapse. Agreeably flavoured, Ostomalt calls for no persuasive coaxing and is really accepted by children and adults alike.



Ostomalt is standardised to contain vitamins A and D in high concentration—i.e. three times that of Ext. Malt with Cod Liver Oil B.P. Its added orange juice provides vitamin C; its malt is rich in vitamin B complex. Entirely free from fishy oils. Teaspoon dosage. In jars 1/9; 3/-. Dispensary jars (more than seven times 3/- size), 17/-.

The Common Cold

AUTUMN INJECTION CAN NOW CONFER WINTER IMMUNITY

Consistent evidence from clinical sources over the past four years shows that the new principles of vaccine therapy established by Dissolved Vaccine G.L. have brought to cold prophylaxis an assurance of majority success. The immunity response to the Cold Dissolved Vaccine G.L. is more consistent, more rapidly developed and of a higher degree because the total antigens are in solution and thus immediately available on injection.
Further, because the antigens are detoxicated, a full dose (½ to 1 c.c.) may be given from the first without fear of undesirable reaction. Three injections at intervals of a week should suffice. The rapidity with which immunity is developed enables prophylaxis of colds to be carried out at any time. It is advisable, however, particularly for patients known to suffer from recurrent winter colds, to administer the vaccine in the early autumn.

FOR TREATMENT Injection of the Cold Dissolved Vaccine G.L. has also achieved conspicuous success in treatment. One or two doses (½ to 1 c.c.) administered in the early stages of a cold will, in the majority of cases, bring about a rapid regression and termination of the symptoms.

THE WIDER ISSUES OF HEALTH LEGISLATION IN INDUSTRY*

BY

LEONARD P. LOCKHART, M.D.

Medical Officer, Boots Pure Drug Co., Ltd., Nottingham; Chairman, Association of Industrial Medical Officers

The new Factories Bill/Act,† in spite of omissions and shortcomings, represents a very considerable advance in social legislation. Under certain provisions health and safety are automatically improved. There are other provisions, however, which depend for their effect almost entirely on the manner in which they are implemented. There is nothing automatic for instance about Clause 11, which provides for medical supervision, nor about those wide new powers of the Secretary of State, nor about Clause 46, which deals with the removal of dust or fumes. The effectiveness of these provisions and of many more will depend to a very great extent not only on the available degree of care and skill, but on a high level of co-operation and of common consent to make the results as good as is humanly possible. It is here that we touch the wider issues of legislation, which can be regarded as of two kinds. It can produce some results by fiat, but, on the other hand, a great deal of modern social legislation defies accurate check and depends for its success on the existence of a widespread desire that in a particular field progress shall be made. Any enactment aiming, for instance, at a higher standard of first-aid work in industry would fall into this latter category. Such a law could be utterly defeated by a variety of factors.

It is not true that the legislature can always be the prime mover in social progress. More probably it is very rarely so. As Benedetto Croce recently said, "Discipline which contains Society instead of being contained in it leads to a suppression of the intelligence." Good laws must follow in the wake of experiment, and it is perhaps true to say that in the social field they act as pegs securing advances pending a new forward movement. They make obligatory on the many what the few have already found to be good practice. To some such an idea is heresy, but it seems the only practical one in relation to a developing system such as modern industry. It is useless to legislate that things shall be done if there are not enough people with the necessary experience to do them. Hence there must always be a vanguard of voluntary effort and experiment before a position is consolidated by law.

Experimental Work

A great deal of experimental work in industrial health has been done by individual employers, and much of what is known as industrial welfare has proved so valuable to the general well-being of the worker that the new Bill/Act is to give to it the force of law (vide clauses 2, 3, 5, 11, 41, 42, 43). It has ceased to be voluntary, and is to become an obligation. Much of the work that is still being done voluntarily and against which the charge of paternalism has at times been levelled is in fact the developing embryo of future law. If it fails to be socially valuable it should be dropped. If it is successful sooner or later it will become a statutory obligation. Holidays with pay, medical and educational services, a shorter working week, the study of incentive schemes, pension arrangements, and feeding facilities are but a few of the fields of experiment at the present time. Without the voluntary activity of certain progressive employers, aided by the co-operation of many of the trade unions, we should not now have acquired the necessary data to form the basis of much of our new industrial law.

To obstruct this voluntary work would be very short-sighted, because experimental laws lead to confusion, and the real social growth cells develop strength only in a free environment. Dr. Lane will later explain to you the details of one determined voluntary experiment which has produced results of profound social significance. The policy of the Industrial Welfare Society has been criticized at times, but looking back nearly twenty years no one can deny that it is the voluntary effort called forth by the Society which has been a most powerful stimulus to progress and which has enabled ideas to become acceptable that ten years ago would have been rejected as unworkable. Without the practical experience of such voluntary schemes the health provisions of the present Bill/Act would have encountered an opposition in Parliament undoubtedly sufficient to wreck many of them. Robert Hyde and his co-workers deserve recognition by our profession.

Under the new Factories Bill/Act undertakings which have discharged their duties faithfully in the light of modern knowledge will find few if any new legal burdens placed on them. Certain things that were formerly done voluntarily will now be done under statute—that is all. The burden falls on those who have hitherto worked to minimal standards. These will have to adopt a new standard, and their competitive advantage over more conscientious firms will be reduced. In the long run such competitive advantage is probably illusory because good conditions and healthy workers lead to sound industrial operations, but on the short view it often happens that a firm working to a low hygienic standard can undersell the more expensively operated concern which increases its overhead costs by giving safer and more healthy conditions of work. Regarded in this way the new Bill/Act will enable progressive minds to work out new advances.

* Read in opening a discussion in the Section of Medical Sociology at the Annual Meeting of the British Medical Association, Belfast, 1937.

† At the time of writing the Factories Bill is still before Parliament. By the date of delivery it is probable that the Bill will have become law.—L. P. L.

Some day these will be enshrined in statute and a new forward step made possible.

Legislative Proposals

The present Bill/Act has made provision for interim advances by granting to the Secretary of State very wide powers (wider than in any previous Factory Act) to make rules and orders having the force of law. It is obvious, however, that the detailed needs of a developing system, such as modern industry, could not be met by constant recourse to the full legislative routine. Parliament has insufficient time and technical knowledge for these urgent but frequently recurring matters. Our public health system would long ago have broken down if the Minister had not extensive executive power, but some form of statutory Advisory Board may be desirable, for it is important that a wide range of knowledge should be available to the Minister, not only when he chooses to call for it, but when the parties most directly concerned desire that it shall be called. This proposal is no reflection on an efficient department served by a body of zealous public servants, but it is the demand that new conditions be met by new methods. Many of the wider issues of industrial health, such as the psychoneuroses and emotional disturbances, together with their physical sequelae, arise not out of unhealthy conditions such as H.M. inspectors are concerned with, but out of methods of work, methods of selection of staff, systems of supervision, payment, and incentive which it might be improper or difficult for civil servants to concern themselves with. The Advisory Board would, however, be free to raise and discuss these matters before they are entangled in prejudice by becoming political questions.

For the time being we must take the Bill/Act as it is and realize that it pegs industrial health and welfare at a higher level than ever before, and that provision will have been made for detailed improvements in that standard pending some future date when a new law becomes necessary. Our interest therefore ceases to be with enactments and becomes fixed upon four bodies of individuals:

1. Those who carry out the provisions of law in industry.
2. Those experts called in to advise or supervise.
3. Those who by research and experiment will pave the way to new advances.
4. Those who teach and in whose power it is to stimulate an intelligent and informed determination to make progress.

The wider issues of health legislation can be summarized in one word—education. This is the task that lies before the present generation. The long fight to obtain recognition of society's duty to its members is all but won. The next task will be more laborious, and it will lack the spectacular victories of the earlier political struggles. It involves raising the enthusiasms of indifferent but not hostile people, passing new ideas into the currency of daily thought and action and bringing about co-ordination between diverse and at times conflicting interests, and, above all, stimulating individual responsibility. The success or failure of the attempt means more than the health of groups of industrial workers. It means the health and ultimate fate of democratic society.

Protection of the Worker

Men and women are still injured, poisoned, and inadequately treated in respect of occurrences in industry that ought not to happen. In some cases there is criminal neglect and in others there is that element of chance which exonerates everyone. Neither of these classes need concern us here. The law can look after the former and improved technique the latter. On the other hand, the great mass of industrial mishaps, maltreatment, or neglect arises because of shortcomings in what one might term "the industrial conscience." Partly this is due to a lack of awareness, partly to lack of knowledge, but very largely to a failure to appreciate the problem in its entirety. The safety and health of the worker must be the paramount interest on any plant or process. The temptation to stop short in the search for proper protection and to hope for the best is strong and must be resisted. Even the worker will sometimes resist protective measures, but then we must go a stage further back and try to find out why. It may be that earnings are reduced if protective gear is used. It may be that prolonged unemployment has reduced skill to such an extent that any further handicap is crucial. The responsibility for solution is then shifted from the technical staff to the general administration or even to the State itself.

Proneness to Accident

Accident proneness may be inherent in the individual, but it may be the result of the impact of a particular system of working on certain temperaments. It may even be that a system comes into general use in a trade and that its effect on individuals is entirely lost sight of. The result may be an increase in accidents or in ordinary sickness, and no medical supervision as envisaged in Clause 11 of the Bill/Act will be able to detect causes unless there is a full appreciation of the possible effects of methods of work on the general health of the worker. A differential diagnosis in such cases often calls for the co-operation of several different people, and for a medical opinion, but whatever the particular trouble any investigation must be a wide one: social issues, personal issues, and often chemical or mechanical issues are involved. A change of foreman may affect an accident rate, beneficially because he runs his shop well, adversely because he harasses and distracts the men. A certain well-controlled and prolonged experiment on the effect of noise resulted in the unexpected conclusion that in this particular case the personality of the supervisors entirely overbalanced the effects of the physically produced noise. It was under the better supervisor that the greatest well-being was experienced, irrespective of the type of machine used.

Personality in Industry

These effects of personality tend to be lost sight of in highly organized plants. The tendency is often to place too much reliance on the physical and too little on the temperamental. Neither must be ignored, but balanced judgement and a good deal of knowledge are essential. Health is a state of poise and internal harmony. It may be upset in a host of different ways, and the results may be seen in increased accidents, increased sick absence, lower production, or even in remote symptoms such as local social unrest. The village in proximity to a pit felt to be a risky one is not in social harmony. These things are not by any means digressions. So much is moving within the industrial organism to-day. So many changes sweep across whole trades and occupations irrespective of single factories that it becomes necessary to link up general health conditions with industrial methods and tendencies in order to get a complete picture of events, and to this must be added the continually lengthening list of chemical hazards. Once, however, safe and just conditions of work have been produced it is deeply harmful to the self-respect, general health, and proper social development of the individual if responsibility is removed from him or her. Unless as individuals we can retain

enough of our personality to achieve personal successes or failures and have some scope for personal adventure in life, we all tend sooner or later to find other outlets for our self-expression; the escape into illness is one of them, and it is by no means generally recognized.

Responsibilities of the Employer

If we are going to look further afield than the actual work in our search for causes of ill-health, hazard, or accident, how far has the individual employer a duty in respect of these conditions? Some are obviously his responsibility, such as the bad selection or inadequate education of supervisors or foremen, and methods of pay that put a premium on taking risks. He also has a duty in certain cases to attend to the transport and feeding of his employees, but in other instances matters are obviously beyond his scope—for example, loss of skill due to prolonged unemployment, rush orders to fulfil contracts for which there is no real urgency, demands from the public for articles which are hazardous to produce and necessary only for the dictates of passing fashion. In many ways the pace at which work is demanded and the sudden changes that occur in the nature of the demand place a very great strain on even the most conscientious employer. After all, if he loses orders his employees lose work, and the whole question of precipitate ordering becomes a social question of some magnitude.

Perhaps enough has been said to indicate the wide range of influences additional to those covered by law that bear upon working conditions and indirectly on the worker. The worker stands at the focal point of a very complicated system of influences, and as things develop the system does not tend to become simpler. It may be that society will be constrained to pause and consider before long whether anyone gains much by the amount of hurried work and whether, conversely, a number of people, particularly the productive worker and those who immediately administer his work, do not suffer a great deal in ways that are as yet beyond the scope of legislation but not beyond the range of that research and inquiry which must, in the nature of things, precede any legislative action. It is certainly true that in many works young employees get a quite inadequate amount of time spent on their training, both technically and in respect of safety.

Medicine and Industry

Medicine in one way and another is coming more and more into intimate contact with industry. The new Factories Bill/Act brings the possibility of medical supervision on a wide scale into practical affairs. The selection of staff, the training of supervisors, and the investigation of production problems have medical implications. It is necessary to know something physiological and psychological regarding workers for particular jobs such as motor driving, flying, and deep-sea diving. Skin conditions, ophthalmic problems, and cardiac efficiency are but three on the physiological list, while the type of worker who is temperamentally unfitted for particular tasks is now receiving much attention. It is no use working these things out if we have no social mechanism for effecting transfers or for absorbing misfits where they will be assets. Misfits are not just psychological oddities. There are also countless physical misfits such as asthmatics, diabetics, orthopaedic cases, and ex-tuberculous patients. We cannot just relegate such people to an industrial scrap-heap. They have a right to be fitted in, provided that for their part they are willing to co-operate in reasonable measures for their welfare. The difficulties at present of dealing with these cases are great, but as they are overcome, or perhaps in order that they may be overcome, we need large numbers of medical men and women who are able to relate medical data to industrial conditions and who understand something at first hand of actual industrial problems. Industry is an intricate affair. It is full of all sorts of anomalies, but not everyone realizes that they are anomalies. It is in this connexion that it becomes so obvious that in general education a biological interpretation should be given so that the future administrators of industry and of the social services could be enabled to appreciate more fully the nature of the problems that face them. Such a question as the shortening of the working week and the increase of leisure has marked biological factors. Working conditions are an integral part of the process of living, and work is a part of life. A proper increase in leisure is essential, but the four-hour or five-hour working day is a myth—not theoretically or economically, but biologically. Somewhere there is an optimum balance between work and leisure which politicians and statesmen cannot determine without a knowledge of the biological and psychological needs of an emergent society. Planning must fit man and not man the planning. The present lack of a biological background to social action is nowhere more evident than in our views on workmen's compensation. An injured man needs temporary financial aid pending cure, or compensation for any permanent loss of earning power and vitality, but he also needs the services of a proper rehabilitation scheme. To stimulate the will to rapid cure and to find suitable work in which the man can complete his cure are twin problems. The longer a man is idle the harder is the process of return to work.

Industrial Training for Doctors

An industrial training for doctors as a postgraduate course with practical experience is essential. The financial difficulties are great, because merely visiting industries is quite inadequate and the proper training takes time. In addition to a study of processes some insight into managerial functions and technique is necessary to enable the doctor to understand the problems of administration. We are but at the beginning of a new phase, and how we deal with it is a matter of very great importance. During the great war the Army learnt that it was essential to bring in the medical staff when discussing major operations. Industry is now in the same phase. It is beginning to take medicine into its counsels and to give it more than a purely research and supervisory function. Progress is slow, but a step in the right direction was taken when the British Medical Association decided to prepare an ethical code for doctors working directly or indirectly in industry. They legislated for a new idea, and the proposals are before the Representative Body at this meeting. They went further when, in order to deal with the wider issues of social medicine, they formed a joint committee with the Trades Union Congress.

Until a few years ago a mere handful of medical men and women surveyed the major medical problems of industry. Mostly civil servants, starting with Thomas Legge in 1898, they laboured without any publicity and with very little recognition, doing a piece of work of which this country has cause to be extremely proud. The certifying factory surgeons did their share of supervision, and now medicine is asked to undertake a far greater responsibility for industrial health. The new Bill/Act lays very considerable burdens on us as a profession, and we must evolve the necessary machinery to train and educate (they are not synonymous terms) doctors for industrial work. Medicine is becoming a function of

management. Employers take medical men and women into their concerns, and in some an administrative and advisory function is combined. The Trade Unions have their own medical advisers, and the great hope is that all these different officers will continue to pull together in mutual confidence and consideration as they now so happily do. The universities are awakening to the need of supplying trained graduates (vide Birmingham and London), and the stage is set for a large-scale advance. This is likely to be rapid once we have overcome the difficulties of co-ordinating the sociological (labour management and health) functions of the small firms. These employ about two-thirds of the insured population, and the new Factories Bill/Act will be a great stimulus to co-operation on labour questions.

Social Implications

To an extent which those outside industry often fail to grasp, the industrial system of to-day is rapidly becoming the social centre of gravity. Many of its problems are primarily in the field of social medicine, not only in regard to the health and welfare of the workers, but indirectly in its effect on the whole social structure and the issues that arise therefrom in the lives and destinies of the bulk of our population. As a profession we cannot ignore the wider issues of industrial health; but we cannot understand them or play our part adequately unless we are prepared to study the industrial structure, from the worker at his bench and in his home to the administrative and technical functions which control his work, and to realize that in the widest sense his health is dependent on many factors, and that any attempt to deal with parts of the problem in isolation must prove a failure. Every preventive and therapeutic measure must be related to some central idea, because the worker himself is not isolated but is a functional part of an intricate system, and his health, happiness, and social efficiency depend on a high degree of technical and cultural co-ordination. Doctors, employers, trade unionists, economists, and teachers must understand each other and work together if we are to evolve progressive ideas which, after due trial, can be turned into the currency of practice, and without which no legislation can be of the slightest avail.

A specification for haemacytometer counting chambers and haemacytometer dilution pipettes has recently been prepared, with the co-operation of the medical profession, by the British Standards Institution. In framing the specification particular attention has been paid to the various tolerances specified. The accuracy of a blood count depends on the skill of the operator in obtaining a representative sample, in carrying out the dilution, and in the use of the counting chamber; it is also limited by the errors of the apparatus employed. The accuracy of the final count depends, *inter alia*, on the accuracy of a number of elements of the counting chamber—for example, accuracy of ruling, accuracy of depth, departure of under surface of cover glass from a plane, etc. In view of the number of possible sources of error the tolerances on individual elements had to be kept small in order to avoid the possibility of a comparatively large error in the final count due to an accumulation of small errors. On the basis of measurements carried out at the National Physical Laboratory on samples submitted by manufacturers as representative of current production, the tolerances were also related to the degree of accuracy attainable in manufacture without unduly increasing the cost of production. Copies of the specification may be obtained from the British Standards Institution, 28, Victoria Street, S.W.1, price 2s. 2d. post free.

THE WIDER ISSUES OF HEALTH LEGISLATION IN INDUSTRY*

BY

R. E. LANE, M.B., M.R.C.P.

Honorary Assistant Physician, Salford Royal Hospital; Medical Officer, the Chloride Electrical Storage Co., Ltd.

My contribution to the discussion is an account of what has taken place in the electric accumulator industry during the last twenty years. It will furnish, I hope, a concrete example of what can be done, and what is now being done, to safeguard health in a dangerous industry, and will give some idea of the importance of individual effort as a complement to legislation.

In the first place I must point out that the particular risk in the battery industry is lead poisoning. In the years immediately following the war the industry began to expand. Batteries were needed for numerous purposes, and new fields opened up for their use. This demand had to be satisfied, and manufacture was undertaken by people with no previous experience of the industry and with little knowledge of the dangers it involved. They found that they were subject to certain Home Office rules and regulations, which they observed, or tried to observe—at any rate in the letter.

Soon it became evident that all was not well. A few workers were taken seriously ill, many looked and felt unwell, and the general standard of health in the industry deteriorated. Men became apprehensive when they heard of their friends suffering from lead poisoning; they became more worried when they saw that some of them were paralysed, could not dress or feed themselves for months on end, and did not return to work for a year or eighteen months. Some sought other jobs, but most carried on. They did what men usually do in these circumstances—they made feeble jokes about the danger, and a certain department became known as "The Dead House." The evil reputation spread to the districts round about, and it became, for instance, a stock joke for the wag visiting the works to misinterpret the notice "Drive Dead Slow." I mention these facts merely to give you some idea of the state of mind that existed among employees—a state of mind that can have produced nothing but harm, and probably caused as much suffering and inefficiency as the actual lead itself.

The larger firms did much to improve conditions, and during 1924 the Home Office authorities, viewing with alarm the rise in the number of cases of lead poisoning, decided that further and concerted efforts must be made. Employers and others were consulted, and the regulations governing the industry were completely revised. These rules, which came into force in 1925, made the best practice of the more progressive firms compulsory on all manufacturers, and regulations were drawn up by the Medical Department of the Home Office based on the vast experience of lead poisoning which they had accumulated in past years from other industries.

These regulations may be said to have brought the practice of the backward up to the level of the progressive firms, or, in Dr. Lockhart's words, "They pegged the advance." There was at any rate to be no slipping back from this level. This was a reasonable standard, and it was to be a minimum standard. Excellent results followed the introduction of this code of regulations; the number of cases began to fall, and has continued to fall ever since. This decline, however, has been assisted by another factor, which I will now describe.

* Read in opening a discussion in the Section of Medical Sociology at the Annual Meeting of the British Medical Association, Belfast, 1937.

Despite the introduction of the 1925 regulations the incidence of cases in the largest and most progressive of the firms continued to rise. This apparent anomaly is easy of explanation. I have already pointed out that the 1925 revision of regulations was largely based on the current practice of the progressive firms, where these regulations had been voluntarily applied for a considerable time. In making the code compulsory, therefore, little change was necessary in the methods of this factory. Their business, however, was growing fast, with a corresponding increase in the number of employees, and since the proportion of cases to employees remained fairly steady it is obvious that the number of cases would continue to rise.

Investigation in the Factory

Here was a difficult problem. The Home Office could not immediately introduce more stringent regulations: it was already working hard to administer the previous code. The employers also were extremely worried at the turn of events. They had spent a great deal of money in their attempt to put things right, and still they were unsuccessful. It was here that the Medical Department of the Home Office went outside the rules and regulations and functioned in its other most important capacity—that of adviser. The Chief Medical Inspector pointed out that the problem needed further investigation "on the spot," and it was suggested that the firm should appoint a medical man who would study the problem in the factory. Fortunately, this company had a board of directors which needed no persuasion that money so spent might reasonably be expected to result in a solution of the problem. At any rate they were prepared to make the experiment, and a medical officer was appointed for three years. He was to study the industry and its particular dangers, and was to make recommendations as to how improvements could be effected.

For his work it was necessary to have facilities for determining the effects of various doses of poison, how this entered the body, and the limits of contamination of the atmosphere which might safely be allowed. This knowledge was used when collaborating with chemists and engineers to produce safe working conditions. In addition it was necessary to elaborate methods for the routine medical supervision of the workers. But more than this was needed; it was essential that hours of work, and in some cases rates of pay, should be adjusted. These matters not only required the co-operation of a management which was fully alive to its responsibilities to the workers, but one which had the will and determination to see that every necessary step was taken. The figures show that the results of the experiment were satisfactory; in fact, they were so satisfactory that these methods were in 1929 extended to other factories in this industry, and with the same happy results. Here, then, we have an example of the wider activities of the Home Office in dealing with problems of this type. Rules and regulations embodying the best-known practice are laid down to ensure a reasonable minimum. Firms are then encouraged to undertake further pioneer work in which advice and expert assistance are forthcoming. This seems an eminently practical method of procedure, and one likely to give good results. To my mind the advisory function of this Government department is a most important one.

It might be argued that the method adopted in the case I have described is not the best method of procedure; that all investigations should be made by a Government body, and that rigid rules and regulations governing manufacture should immediately be based on these findings. The charge of paternalism might even be levelled at this industry, and at the methods it has adopted. Such a charge, however, can be easily met. It should surely be required of any employer that he should provide safe conditions of employment for his workers. If the public demands an article the manufacture of which involves expensive plant and an expensive organization, it must expect to pay a correspondingly high price. Attempts to cut prices at the expense of the worker's health were the habit of industry in the past, and it would seem that one of the biggest advantages of any large combine is the power it possesses of keeping prices at a level which will enable the worker to be adequately provided for in the matter of healthy working conditions. In this connexion it is interesting to note that in a recent trade agreement of which I have knowledge general collaboration upon measures for health protection was specifically agreed upon.

Need for Concerted Effort

Dr. Lockhart contends that the long fight to obtain recognition of society's duty to its members is all but won. This is true. What is now needed is a concerted effort to implement that recognition. There are still far too many individuals who evade the responsibilities the community rightly expects them to carry. There is no doubt that some of the smaller firms provide the best possible working conditions—conditions and relations which are only possible in a small undertaking, but unfortunately the converse is also true: many of the very worst conditions so far as dangerous trades are concerned are found in small firms. In some cases this results from the necessity to cut prices, and where this is so an attempt is often made to reduce overhead expenses by curtailing necessary health services. In other cases personal selfishness influences policy. No education of the individual employer will entirely overcome this attitude where it exists. He must be strictly controlled by legislation, which must not lag far behind the most progressive practice. He will then be obliged to provide reasonable conditions for his employees, but the standard can never reach the level that is actually attainable unless the attitude and outlook of this type of employer is overcome. Public opinion can do much towards providing the necessary stimulus, and the trade unions must undoubtedly co-operate. Hitherto the unions have been largely concerned with obtaining an improved standard of money wages. As time goes on, however, they must also co-operate closely in an effort to procure the best working conditions for their members, which means the development of scientific advisory functions.

It is well-nigh impossible to introduce legislation which will provide for all contingencies. For instance, it will be remembered that recently in the House of Commons an amendment to the Factories Bill was introduced suggesting that "safety first" committees be made compulsory, and it was evident that the general feeling in all parties was that probably this was undesirable and that regulations making them compulsory would be likely to do more harm than good. Exactly the same argument applies to much that is done in the dangerous industries. Legislation is able to go a great deal of the way, but final success depends largely upon the employer and upon his outlook, and—what is often forgotten—upon the co-operation and support of the employees.

The Trained Medical Officer

An employer willing and anxious to provide the best working conditions for his employees will in many cases need expert medical advice. If he is prepared to accept this advice he will find he avoids many pitfalls. An

interesting example recently came to my notice. A small factory which had been carrying on quietly and safely for many years decided to introduce so-called efficiency engineers to improve its methods. This resulted in turning out rather more material per man-hour, but at one stage a very large proportion of the workers were down with lead poisoning. In this particular instance, had a trained medical officer with adequate industrial experience been asked to co-operate with the engineers it is certain the "speed-up" could have been carried through without such disastrous results to health.

How is the employer to obtain this advice? Much may be procured directly from the Home Office authorities. Where, however, experimental work is necessary this may now be carried out at either London or Birmingham University, where a department of industrial hygiene has been opened. In other instances the problem might be investigated by the Industrial Health Research Board, which, as you know, is administered under the Privy Council. The problems investigated by the Board are usually of fairly wide application, and the findings can be of value over a large range of occupations or industries. In many cases it is important to have a completely impartial body, and one of high scientific attainments. It is a good thing, for instance, that the investigation of the incidence of gastric sickness among busmen was started by the Industrial Health Research Board some four years ago and was completed before the question became controversial. Whether or not the pioneer work is best done by University bodies, by the Industrial Health Research Board, or by the industry particularly concerned may be a matter of opinion, but that it must be done by someone is obvious. Most people will be ready to agree with this contention in the case of the dangerous trades. The figures available are convincing evidence that a danger existed, and that certain steps were successful in overcoming the danger, while the most obstinate director is likely to be convinced of the value of this type of work when he finds that it is actually saving him money and that his medical department is costing rather less than he had previously spent on compensation. It is perhaps not so easy in ordinary industry to convince the sceptic that these methods are necessary, but those of us who are in close contact with the medical side of industry know that it is just as important for these industries as for the dangerous trades.

Commentary

I hope I have made it clear that in order to obtain real and final success the attitude of the employer must be the correct one, and the worker must be co-operative. The education of both employers and workers in these matters is of vital importance, and it is only by improvement in both and by the general education of public opinion that we can establish the best conditions in industry. This education is going on and conditions are improving steadily, but it behoves all who are interested in the public health to see that this education grows and flourishes. It appears to me that this means that the medical profession must take a much greater interest in these health problems, and must make an effort to acquire a real and accurate knowledge of industry's needs in this sphere.

A large cancer institute with an experimental department, hospital, and out-patient department has recently been founded in Buenos Aires, with a branch at Bahia Blanca. It has been found that only 3 per cent. of the patients seek advice in the first month, as compared with 86 per cent. after the end of six months.

THE WIDER ISSUES OF HEALTH LEGISLATION IN INDUSTRY*

BY

ERNEST BEVIN

It is a gratification to the great trade union movement that the industrial health problem is receiving much closer consideration than at any period in its history. The problem has given our movement much anxiety and has involved considerable expenditure of money and effort in bringing about investigations to secure the scheduling of industrial diseases.

Opportunity for a Co-ordinated Service

With the passing of the Factories Act, although in many respects it falls short of our desires, and the placing of the industrial health problem on a more organized basis, an opportunity is presented for a really co-ordinated service which, for the first time, can be made universal in its application. We agree that a large contribution has been made by voluntary effort. It is true that it may have been introduced from a variety of motives, possibly paternal, or from the point of view of economic efficiency; or schemes may even have been conceived with an idea of handicapping our own movement. But motives do not always govern achievements or determine the effect of a course of action which may be taken. The net result has been to produce sufficient evidence to enable the State, employers, and trade unions to approach this problem and place it on a more organized basis, co-ordinating all the contributing factors and linking it with a complete medical service which, if handled correctly, will become a great national asset.

The Health Problem and Capital Values

If the health problem could be viewed from the point of its capital value it would be possible to arrive at a better estimate of the result to the nation of its neglect, for it must be remembered that the only capital a worker has is his skill and ability to work. Therefore if the capital loss could be calculated in terms of depreciation, as is done in the case of machinery, the facts would be such that, applying the same result to the mechanism of a works, the industrial management would call in the best scientific and engineering ability at its command to remedy the loss. I suggest that the loss of value resulting from the lack of proper standards for the health of the worker, if it could be translated into capital, would represent a greater total than would appear under any other head. No attempt, however, has been made to calculate the actual capital value of an efficient worker, as represented in output and gain to the community. In addition, the loss is extremely far-reaching, for whilst a machine may depreciate, its effect is limited; but physical deterioration of the worker has a very grave repercussion upon his home, on the well-being of his family, and on his general environment.

We welcome the consideration of the industrial health problem from yet another angle. For a long time it was assumed that the main thing to be decided in the case of a worker who was ill was whether or not he was a malingerer. Practically the whole of the Workmen's Compensation Laws and restrictions associated with certain health services have been based upon the assumption that protection had to be secured against exploita-

* Read in opening a discussion in the Section of Medical Sociology at the Annual Meeting of the British Medical Association, Belfast, 1937.

tion on the part of the worker, and to that extent the service has been handicapped in its outlook. I am not too sure that the attitude of the medical profession itself in the past has not been coloured by this conception. Happily, however, with the growth of the study of psychology and a deeper understanding of the industrial health problem, this approach has to a large extent been changed. Housing and the habits of the people themselves have also been a great stumbling-block.

The Works Doctor

Another difficulty which has handicapped us in dealing with the medical examination of work-people has been the attitude of the people themselves towards the works doctor, and the works doctor's attitude towards the work-people. It must be remembered that in many public services and large works the works doctor is looked upon as the person employed by the management to protect its interests. For instance, in one great undertaking if a man is away ill for a period of three weeks he must be specially examined before returning to work—not for the purpose of finding out the cause of illness, but to ascertain whether he is fit for the particular occupation upon which he is engaged. The result of this has been to create fear in the minds of the workers, and they try to get back to work within the specified period even though they may not have fully recovered. Had I time I could mention many other examples. In order to protect men undergoing medical examination my own organization has found it necessary to establish agreements making provision for the union to submit the worker to a second doctor if it is not satisfied with the decision of the works doctor; then, if agreement cannot be reached, to a medical referee. While this is necessary to protect the individual, the psychological reaction on the man is not conducive to his recovery.

Welfare Work

The same difficulty is experienced in connexion with welfare work. This has been very useful in some cases where there has been a common understanding. On the other hand, where it has been introduced without the union and in antagonism to them it has produced quite a bad reaction. For these and many other reasons I welcome the opportunity now presented for a complete overhaul of the whole medical service and the establishment of a branch which might be designated an industrial medical service.

Another great difficulty with regard to the health factor is that before steps are taken to remedy an existing evil one must establish a prima facie case by comparison with other controlled groups. This seems to be a fetish of the medical profession. The matter was brought out very clearly in the recent London bus situation. In 1928 I saw the difficulty which was arising: here was a body of men with a high physical standard of health who were beginning to show certain intensified nerve reactions different from those that had hitherto existed, and I pressed for an examination of the matter. It took me from 1928 to 1934 to get it into a position for a proper study to be made by the Industrial Health Board of the Medical Research Council, and the report of the investigation has only just been issued—in July, 1937, a period of nine years.

The Study of Health Problems

We want a service which will study health problems immediately they arise in industry and take measures to safeguard the health and welfare of the worker, remembering that prevention is better than cure. Very often a worker, for economic reasons, will suffer a long time before acknowledging he is ill and going to a doctor. Even then the ordinary medical practitioner has little time to study the complaint seriously, and may have only a slight idea of the effect of industrial conditions upon the health of his patient. Similarly the union, until it receives complaints from a sufficient number of its members, has little or no knowledge of the insidious development of factors undermining the health of the people. We must therefore try to ascertain the best way to take advantage of the new conception of health measures, to profit by our past experience and difficulties, and to tackle the health problem at its source.

Suggestions for a Co-ordinated Service

We should be reluctant to see a new segregated medical service established. It must be remembered that while we have exerted considerable pressure to bring factory legislation up to date, the workpeople and industry generally are paying a substantial sum per annum for a medical service which, in the general view, is not yielding the results we are entitled to expect. I am hopeful that ere long the new Joint Committee of the British Medical Association and the Trades Union Congress, together with the Departments of State concerned, will examine the whole problem with the view to ascertaining the best possible form of organization to establish: (1) a co-ordinated medical service: (2) a comprehensive research organization; (3) a reorganized panel service; (4) a more rapid and practical application of scientific discovery to the needs of the medical service.

The bulk of medical practice in this country is concerned with industrial workers. How can this be linked with the industrial medical service we contemplate? Taking the great hospitals as a centre, I should like to see the following experiment made:

(*a*) Twenty or thirty medical practitioners pooling the whole of their panel patients.

(*b*) The State or public authorities providing the necessary building accommodation and equipment for the setting up of a special clinic.

(*c*) Each medical practitioner, whilst continuing as a general practitioner, having an opportunity to specialize on some phase of industrial medical work.

(*d*) Works doctors participating in the work of the clinic and acting as part of the General Practitioners' Service.

(*e*) Close contact between clinics, hospitals, and research institutes, and every possible facility given to the carrying out of such work.

(*f*) Arrangements made for the diagnosis of the various cases to be sent to the appropriate research institution for investigation and record, and the prompt application of the most up-to-date treatment.

A better knowledge of the causes of illness in particular groups and classes of workers would soon be available. For instance, in looking over some of the last returns of the Registrar-General I find we have one of the highest tuberculosis mortality figures among dock labourers. The reason for this is a question not easily answered, but the high mortality figure is a definite fact. Is it due to the nature of the employment, to malnutrition of the workers, to irregular hours of work, to climatic conditions or exposure; or what is the reason for it? Similarly other industries have their specific diseases.

A detailed analysis and record of illnesses and diseases experienced in various sections of industry would be of tremendous value to the research institutes and to the

medical service. Details could also be supplied to the various Joint Industrial Councils throughout the country with regard to the trade or industry covered, and both sides would be compelled to discuss the difficulties existing; we should then get co-operation between the lay and medical mind in the promulgation of remedies.

Conclusion

The trade unions of this country, whilst asking for the most efficient medical service, are more concerned with prevention than with cure. It has been a great struggle for us to secure facts and data, and I do suggest to the great medical fraternity that individualism has been one of your greatest handicaps. Can you not concentrate your efforts and co-operate with us? If this is possible I am sure that industries will not limit their consideration to wages and hours alone. When discussing conditions of employment they will have before them a new basis upon which to work, resulting in general provisions for dealing with health problems being incorporated in the industrial structure.

As I said at the outset, our chief concern is to maintain what is, in fact, the capital value of our members, with ability to enjoy good health, preserve a high standard at home, rear strong and healthy families, and avoid the waste and loss of illness.

I appeal to the great medical service and to my own people to set aside all prejudices of personal outlook and make one great combined effort to establish a really correlated service that will remove one of the blots from our civilization.

THE USE OF ADULT SERUM IN MEASLES

AN ACCOUNT OF AN EPIDEMIC IN A PUBLIC SCHOOL

BY

SIR KAYE LE FLEMING, M.D.,

Medical Officer, Canford School

The following report of an epidemic of measles in a public school of three hundred boys with an age group of 13 to 18 years in which treatment by adult serum was used will be of special interest to all medical officers of schools as well as to doctors in general practice.

The school having escaped an epidemic of measles for several years the risk had been steadily increasing, and on January 15 we started the term with ninety-nine boys at risk of measles. On the 17th a boy was admitted to the sanatorium with a high temperature, and the next day he showed the typical rash of measles. The case was not severe: on the fourth day the patient's temperature was normal, and on the twelfth he was able to go home for a few days' convalescence.

Meanwhile the school had been infected, and the question of using adult serum in the hope of attenuating the disease in consequent cases was considered. The head master gave enthusiastic support to the suggestion, and steps were at once taken to obtain a supply of serum. Through the good offices of Dr. E. H. T. Nash of Hounslow we were put in touch with Drs. O'Brien and Parrish of the Wellcome Research Laboratory, by whom we were supplied with 100 doses of 10 c.cm. each. To replace the stock we undertook to return the equivalent in blood from selected adults. Members of the teaching staff readily volunteered for this purpose. The next step was to circularize parents and obtain permission to use serum. Consent was in the main readily given, but fifteen refusals were received. This number made a useful group of controls.

The most difficult point of all now arose—namely, to whom to give the serum and how soon? Supposing we were lucky enough to have escaped widespread infection and had meanwhile given serum to all at risk, we should very much have compromised our position in dealing with a future epidemic on the same lines. In the first instance, therefore, we decided to give serum only to those boys who showed a rise of temperature, or were +++ risks—a plus standing for dormitory, house, or form contact. The temperature of each boy who had not had measles was recorded daily. It was recognized, of course, that serum used in any but the earliest stage of incubation was probably of little use; but as it could do no harm and experience had not yet crystallized on this point, it was decided to proceed on these lines.

The course of events very soon clarified the position, and a fortnight later cases began to come in so freely that on February 14 serum was given to all who were susceptible. In the end seventy of the eighty-five cases were so treated. The object of this report is to be as helpful as possible to the head masters and medical officers of boarding schools, and in weighing the conclusions here arrived at it is important to bear in mind the following points:

1. That this is the first occasion on which the treatment has been used in a public school, and we were without experience to guide us.

2. That though the number of cases was large for a school, it is small for statistical purposes.

3. That the writer has had experience of at least three equally large epidemics at the same school under similar conditions.

4. That it is not always easy to give proof of clinical impressions even where those impressions are well marked.

The most important conclusion is that the serum proved all the help that we anticipated, and more. The attenuation of the disease was remarkable, and we shall certainly use the method in future. The load of anxiety a school medical officer has to carry during an epidemic of this nature must be experienced to be understood. With this adjunct to his armour of defence the doctor is materially relieved of that load.

Results

The examination of the records of the cases for statistical purposes supports the general conclusion arrived at very definitely, but the impression from clinical observation was even stronger.

The cases fall into three groups:

1. *Serum Not Given* (15 Cases).—This group includes the original case and one boy who was reported to have had measles as a child. The average period of pyrexia for these cases (excluding complication cases) was 8.2 days. The complications that occurred were one extremely severe case of bronchopneumonia (in oxygen tent fourteen days), and two cases of middle-ear inflammation necessitating paracentesis.

2. *Serum Given During Incubation* (20 Cases).—The average pyrexial period was 6.5 days. The complications were four cases of middle-ear inflammation necessitating paracentesis. Of these one was inoculated thirty-six hours only before the rash appeared, and should really rank with Group 1 as a complication. The remainder were injected ten, twelve, and thirteen days before the rash appeared.

3. *Serum Given Before Infection* (50 Cases).—The average period of pyrexia was 5.2 days. There were no complications

The freedom from complications in the whole series is remarkable, although the epidemic did not appear to have been one of a milder type than usual, as indicated by the cases which were not inoculated.

Observations of Attenuation

The following conditions were observed to be attendant on the use of the serum:

1. Lower temperature, fewer constitutional disturbances, quicker recovery.

2. The rash is noticeably different. It is much more discrete, rather more ham- or copper-coloured. It persists a long time on the face and is not so profuse or well marked on the trunk and limbs.

3. There was at first a suspicion that the incubation period is delayed; the rash appeared slow to come out, even for measles. This suspicion was not borne out by subsequent observations. We had, in fact, been prepared to accept the view that the serum conferred some degree of immunity when used before infection. The steady curve of the incidence graph does not support this. The inoculation of fifty boys on the same date might be expected to produce a definite flattening of the incidence curve if temporary immunity was a result of inoculation.

The real problem in aiming at attenuation in this type of school is to select the right moment to give the serum. The ideal from the treatment point of view would be the certain infection of the largest number from the first case. In a preparatory boarding school it would probably be wise to use serum without delay.

There is no reaction to the injection. It is well to give it before bedtime. There is some stiffness locally some four hours after injection, and a few boys were allowed to stay in bed for breakfast. Two patients had chicken-pox concurrently with measles.

In all cases with ear symptoms of deafness, discomfort, or pyrexia the drum is incised as soon as any bulging is observed. If the fluid evacuated has passed the serous stage we are disappointed at not having been earlier in intervention. The importance of the early treatment of middle-ear inflammation is not sufficiently insisted upon in the standard works on medicine used by medical students. It is worth recording in this connexion that in fifteen years' experience of measles epidemics in this school we have never had a case of mastoid infection requiring operation.

Conclusions

The use of adult serum has a marked effect in attenuating the disease and in decreasing the incidence of complications.

In the epidemic here recorded there was no evidence of temporary immunity resulting from the use of the serum. Early treatment of middle-ear infection by incision of the drum will greatly reduce the risk of mastoid infection.

The *Transactions of the Twenty-third Annual Conference of the National Association for the Prevention of Tuberculosis*, which was held last July in Bristol, have now been published from Tavistock House North, Tavistock Square, London, W.C.1, as a paper-covered volume of nearly 200 pages (price to booksellers, 6s. 9d.; sold privately at 7s. 6d.). The main subjects discussed were propaganda and publicity methods, preventive institutions, with special reference to open-air schools, and the equipment and activities of a tuberculosis dispensary.

THE VALUE OF CONTINUOUS NEGATIVE PRESSURE IN SURGERY

BY

M. J. BENNETT-JONES, Ch.M., F.R.C.S.

Honorary Surgeon, Bootle General Hospital; Visiting Surgeon, Whiston Infirmary, Lancashire County Council; late Resident Surgical Officer, Liverpool Royal Infirmary

The use of suction to remove blood, pus, and other exudates in throat, abdominal, and neurological surgery is now well established. Through a bronchoscope or oesophagoscope no other method would be possible; in brain surgery it is essential to keep a bloodless operative field with the minimum of trauma to the tissues. For such purposes suction pumps are required which will remove a large quantity of fluid quickly, while the amount of noise such a pump produces is of minor importance because it is only used in an operating theatre for relatively short periods. There are many excellent pumps for these purposes which work by pedal, electric, and water power.

Suprapubic Drainage

Although the Harris operation is accepted as an advance in suprapubic prostatectomy, an attempt at the immediate closure of the bladder is advocated by only a small proportion of surgeons owing to the risk of reactionary haemorrhage and the difficult and constant after-treatment necessary. The large-calibre indwelling catheter required is very liable to give rise to a severe urethritis, which later may lead to stricture formation. Suprapubic drainage is regarded as much safer, especially in the hands of the majority of surgeons. Can, therefore, the disadvantages of suprapubic drainage be removed? There are roughly two ways of treating a suprapubic cystotomy. The urine can overflow through and around a tube, to be collected by a suprapubic box. The main advantage of this method is that the apparatus is so simple, but the disadvantages are many. Macalpine (1932) pointed out that overflow drainage of the bladder predisposes to perivesical extravasation, which contributes to toxaemia in a patient whose excretory function is usually already damaged. He has shown that post-operative uraemia and sloughing of the wound are often the result of overflow drainage of the bladder: "the fundamental fault is the saturation of the perivesical structures before any of it arrives on the surface of the abdomen." He supported his assertions by experimental and clinical evidence, and also by the marked improvement in his results since he used suction drainage. Although suprapubic wounds frequently heal well without the use of suction, especially in private patients in good condition, I have also been convinced of the improvement in the morbidity and mortality resulting from the use of suction suprapubic drainage. I have based my opinion on a number of cases at the Liverpool Royal Infirmary and other cases treated elsewhere during the last three years. Furthermore, if a suprapubic box is used early it has to be applied with firm pressure in order to prevent leakage; such pressure causes much pain in a recent wound, which becomes oedematous and gaping, thus also predisposing to infection and violating Hilton's principle of rest to a healing wound. The other alternative of allowing the urine to soak into repeated large dressings and the bed is an "incomparable disgrace to modern surgery."

Problem of Suprapubic Suction Drainage

Even in 1914 Chetwood described an electric suction pump operated by a 1/12 horse-power motor; this apparatus

also included a pressure gauge with a regulating device. Although this elaborate machine worked well I think it was too cumbersome and expensive to be tried by others. In 1916 Churchman described a rotary electric suction pump, but very few details are given about its use. A most ingenious apparatus was also devised by Davis (1916); this was introduced into the Liverpool Royal Infirmary by Professor R. E. Kelly, but it was soon given up because it leaked. The apparatus consisted of a large glass bottle which was exhausted by a vacuum pump: the vacuum was gradually reduced by a very fine capillary tube, thus producing negative pressure for a long time. Various hydrostatic pumps (Jordan, 1936) have been used even longer, but most of them are cumbersome, and they have usually been discarded because they have failed to carry over clots. I was amazed to find that a pressure of at least 10 cm. of mercury is necessary to be certain of bringing urine and blood clot through a tube with a 3/8-inch internal bore: this fact explains why the Cathcart type of pump is quickly abandoned. The Bunsen aspiration pump which is fixed to a cold-water tap is powerful enough, but it can only be used in a hospital bed specially fitted up, because the noise of running water would disturb patients. With this type of pump the rate of suction is far in excess of what is required if enough pressure is obtained, for the rate of suction increases with the amount of negative pressure according to the rate of water flow from the tap. An excessive rate of aspiration tends to cause unnecessary gurgling in the wound, cooling of the bladder, and accumulation of urinary deposits in the tube unless irrigation is arranged. However, the great advantage of this type of pump is reliability, unless the water supply fails or fluctuates.

The problem is therefore the removal of only about 50 oz. of urine in twenty-four hours, but it is mixed with blood clot and possibly diluted with a variable quantity of irrigating fluid. Suction should start *immediately* after the operation and be continued for at least three days; by that time one hopes that the perivesical tissues have become walled off and the wound has had a chance of healing under a dry dressing. Macalpine advised aspirating every quarter of an hour, removing about 1/2 oz. of urine each time. Although theoretically this should keep the patient dry, allowance has to be made for coughing, change of posture, and the unavailability of the nurse every quarter of an hour, so continuous aspiration is better. I also have the impression that there is less bleeding from a bladder which is kept empty.

For the last few years I have been trying to construct a satisfactory negative pressure apparatus, because I believe the lack of one is the reason why suprapubic suction drainage of the bladder has not been widely adopted. A serviceable apparatus should be capable of producing any degree of negative pressure up to 25 cm. of mercury, with an adjustable suction rate: the rate of suction required is very much less than that of the usual electric pump. The difficulty has been to construct a pump which possesses qualities of being reliable, almost silent, easily portable, compact, and preferably capable of working on both the direct and alternating main electric current so that it can be used anywhere suitable for nursing patients.

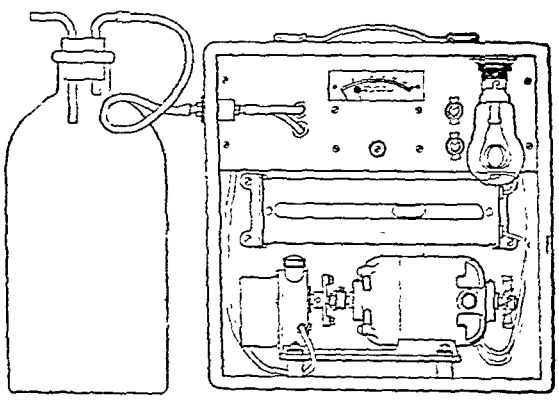
Methods of Applying Suction to the Bladder

It is important to keep the bladder almost dry and yet avoid any possibility of the mucosa being drawn against the end of the tube—that is, atmospheric pressure must prevail in the bladder by arranging for a down draught of air. This is usually secured by having a right-angled glass suction tube fitting loosely in the rubber bladder-drainage tube; the glass tube must be slightly shorter than the rubber tube. Another excellent method (Macalpine, 1932) is to pierce the rubber tube with a silver cannula or a long exploring needle, which also must not reach the end of the rubber tube. Whichever method is used lateral eyes are necessary in the distal end of the rubber tube: the second method is better when a very small rubber drainage tube can be used. Irrigation of the bladder is easily arranged by allowing a mild antiseptic solution to enter through the air inlet tube or a tube incorporated in the rubber drainage tube—for example, Marion's tube. One may prefer to pass the irrigating fluid per urethram. Irrigation at the rate of about one drop per second certainly hinders clot formation and the deposition of phosphates in the tube, but it makes the urinary output estimation more difficult. This estimation is, however, more of prognostic than of therapeutic value. It is difficult to say at present whether the irrigated cases did slightly better than the non-irrigated ones, but I think they do.

Empyemata

In 1890 Bülau advised siphon drainage of the chest because he considered that steady removal of pus and a steady intrapleural pressure caused less shock and assisted expansion of the lung. Immediate open drainage appears to have been the accepted method of draining empyemata until the work of Graham and Bell for the Empyema Commission emphasized the dangers of the open pneumothorax in synpneumonic empyemata (Morriston Davies, 1930).

Closed drainage does not necessarily mean intercostal drainage, but it implies that negative pressure is present in the drainage tube. An absolutely gas-tight junction between the tube and the chest wall is essential for successful production of closed drainage if a water seal or some other hydrostatic (McEachern, 1933) method of producing negative pressure is used. Intercostal drainage certainly makes it easier to obtain a gas-tight junction, but the small tube it entails prevents the proper drainage of thick pus and fibrin. Roberts (1935) stated that repeated aspiration through a needle is inferior to closed drainage because the cavity cannot be emptied of fibrin, also the filling up of the cavity between aspirations fails to reduce toxaemia and to allow the lung to expand. Moreover, repeated aspirations every forty-eight hours distress a patient, and especially so if infection of the chest wall occurs.



Closed drainage has many advantages over open drainage. The danger of the open pneumothorax, before the fixation of the mediastinum, is obviated. This applies especially in children, in bilateral cases, and in the synpneumonic streptococcal empyemata with thin pus. The negative pressure in the pleural cavity assists lung expansion, and therefore shortens the period of drainage required.

Closed drainage suffers from the disadvantage that the patient may pull out the tube, but this can be prevented by suturing the external flange of a Tudor Edwards (1931) tube to the skin and then using strapping to prevent the tube slipping through the external flange. In narrow intercostal spaces the pressure of large drainage tubes may cause necrosis of the adjacent ribs. It is better to resect a rib in all cases to ensure adequate drainage by a large tube, because rib resection need not prevent successful closed drainage. If a faulty siphon apparatus or a water seal is used fluid may be sucked into the chest, but

surely this is a fault of the apparatus and not of the principle of closed drainage.

The usual method of closed drainage operation is to pierce the chest wall with a trocar and cannula, followed by the introduction of a Pezzar catheter. Although Bettman's thoracotome (1933) enables a larger catheter to be introduced, I have mentioned the advisability of rib resection in most if not all cases. The "flapper" tube (Bohrer, 1934) is far too dependent on the gas-tight junction between it and the chest wall to be effective; also it can only cause negative intrapleural pressure during inspiration.

The Tudor Edwards drainage tube is probably the best because it is large enough to drain thick pus and it possesses an internal flange which greatly helps to maintain a gas-tight junction. If the chest wall is tightly closed round the tube and perhaps reinforced by a collodion-and-wool dressing there will be very little leakage. If, however, the tube is connected with a water seal the slightest leak will cancel all the negative pressure, which as a rule is a few inches of water only during inspiration and coughing. I have therefore tried the effect of a more constant negative pressure with my suction apparatus. A constant pressure can be maintained by placing a large bottle, the volume of which is considerable compared with that of the pleural cavity, between the suction-apparatus and the large drainage tube. A constant intrapleural negative pressure of 30 mm. mercury should keep the diseased lung practically at rest in the expanded condition. So far I have not treated enough cases to give statistics, but it appears very satisfactory. I believe that in the past we have been afraid to apply sufficient negative pressure to the pleural cavity. I have also had the opportunity to apply 30 mm. mercury pressure to the pleural cavity after

A portable continuous negative pressure apparatus.

a lobectomy had been performed by Mr. Hugh Reid for the first week after operation. During this time there was no effusion and practically no bleeding, while the general condition of the patient was excellent. I believe that this pressure helped to prevent collapse of the remainder of the lung with the necessary sequel of pleural effusion or empyema. This complication of lobectomy was discussed at a recent meeting of the Association of Surgeons, but no effective preventive measure was suggested.

Summary

1. The value of suction suprapubic and closed empyema drainage has been confirmed.

2. An attempt has been made to construct a suitable negative pressure apparatus for the after-treatment of suprapubic cystotomy, empyema, and lobectomy.

3. I have tried to point out that suction needs analysing into its components of pressure and the volume evacuated with respect to time, in order to suit the particular purpose required.

I have to thank all the surgical staff of the Liverpool Royal Infirmary for allowing me to try out the above methods on their cases. I am also much indebted to Mr. J. L. Mayhook, B.Sc., A.I.C., for his untiring efforts in designing and constructing the pumps that have been used. The present one, which has proved most satisfactory, is a gear pump worked by a universal 1/16 horse-power motor with a pressure gauge graduated up to 30 cm. mercury. The pressure can be adjusted to the required amount by a blow-off device incorporated in the pressure gauge, while the rate of suction is controlled by a rheostat.

BENZEDRINE: A REVIEW OF ITS TOXIC EFFECTS

WITH THE REPORT OF A SEVERE CASE OF ANAEMIA FOLLOWING ITS USE

BY

IVOR J. DAVIES, M.D., F.R.C.P.

Physician to the Cardiff Royal Infirmary

Benzedrine is the name given to a synthetic drug (β-phenylisopropylamine) chemically allied to adrenaline and ephedrine and comparable to them in its pharmacological effects. Prinzmetal and Bloomberg (1935) introduced it into the treatment of narcolepsy, as they had found it to be much more effective than ephedrine in this condition. Guttmann and Sargant (1937) recently reported further observations on benzedrine of an experimental and therapeutic nature which had been collected since the preliminary communication on this subject from the Maudsley Hospital by Peoples and Guttmann (1936). Their investigation was mostly confined to the action of benzedrine on the cardiovascular system and the psychological changes observed. Benzedrine produces a general psychological stimulation, and subjectively this is shown by increased confidence and initiative, and ease in making decisions, but is sometimes combined with a feeling of restlessness. They describe the psychological effects in detail, and further state that medical colleagues and others who have themselves taken benzedrine have found it of definite value in such tasks as lecturing or taking an examination. Their experience is that mild depression accompanied by retardation is the most favourable of all psychological disorders for benzedrine therapy. In conclusion, they warn against the possibility of addiction and are already aware that the drug is obtained without medical supervision. At present benzedrine may be purchased without prescription. As they say, this seems inadvisable with a drug the properties of which have still to be fully investigated. They emphasize the fact that the therapeutic indications for the use of benzedrine, apart from the treatment of narcolepsy, have not yet been formulated exactly.

Anderson and Scott (1936) have reported the cardiovascular effects of benzedrine. The patients selected for

the study were mild neurotics and psychotics, but were physically fit. The drug was given in amounts ranging from 10 to 30 mg. A certain number of normal subjects were also investigated. Pallor, flushing, palpitation, and both increases and decreases in the pulse rate and blood pressure were noticed in some of those receiving benzedrine, and in six recorded cases the effects included collapse, multiple extrasystoles, heart-block, and pain in the chest radiating into the left arm. In a case of involutional depression with paranoid ideas, severe cardiovascular effects of the administration of benzedrine were observed. After some mild preliminary symptoms over a few hours, this patient suddenly collapsed. The pulse rate was slow (56), and examination showed a 1/4 heart-block with an occasional extrasystole. Gradual recovery ensued during the following twenty-four hours. The patient's cardiovascular system on admission showed nothing abnormal, nor was there anything to indicate the likelihood of the severe reaction induced by the drug. Those authors quote Myerson and Ritvo (1936), who reported a severe reaction with collapse in one of their patients. Myerson, Loman, and Dameshek (1936), recording the results of administering 9 to 50 mg. of benzedrine subcutaneously to eighteen mental patients, state that "slight cardiac arrhythmia appeared in four cases. This was either of the sinus type or due to extrasystoles." Their intensive investigations demonstrated marked effects on the cardiovascular system and included a variable rise in the red and white blood counts without change in cell volume or haemoglobin content. Anderson and Scott conclude that until more precise knowledge of the cardiological effects of benzedrine are obtained caution should be exercised in the administration of doses of 10 to 20 mg. or more, particularly in elderly subjects and because detailed cardiological investigation of the effects of the drug appears desirable.

In an annotation on Anderson and Scott's report the *Lancet*, in the same number, comments: "If benzedrine does all that is claimed for it already, it is pretty certain, if used repeatedly, to produce some undesirable effects as well." That journal also referred to Myerson, Loman, and Dameshek (1936a), who mention a mysterious and astonishing polycythaemia—ten million red cells per c.mm.—produced on one or two patients by a daily dose of 40 mg. for ten days.

J. H. Fisher (1937), referred to the article of Anderson and Scott. The effect of benzedrine on normal persons was investigated at the Southend-on-Sea General Hospital on eight members of the resident staff. All of them showed a moderate rise of blood pressure, which returned to normal after four hours. The pulse rate in the majority of cases showed a slight increase after half an hour, but later was slowed in all individuals, and was slowest one and a half to two hours afterwards, when the blood pressure was highest. The slow rate while sitting was very unstable, for the least exertion caused a great increase. The only unpleasant feelings noted were by two individuals who on standing up had a transient feeling of faintness. The pulse rate in both had suddenly increased to about 130. The euphoria was well marked in all, and after one and a half hours' conversation was at a maximum. The drug was taken in a 30 or 40 mg. dose by the mouth at 8 p.m., and its effects on sleep were well demonstrated. The amount of sleep varied from two to three hours to none at all.

D. M. O'Connor (1937) reported a case where a striking fall of blood pressure and apparent sphincter spasm followed the administration of this drug in ordinary doses over seven weeks. S. Levy Simpson (1937) in a comment on an annotation in this *Journal* (1936, 2, 1204), where it was stated that the drug also caused a rise in the red and white blood counts, referred to some experiments made by him and B. H. E. Cadness on guinea-pigs (1936) from which they concluded that "ephedrine probably causes extrusions into the circulation of erythrocytes, leucocytes, and platelets from the storage and haemopoietic centres, including the bone marrow." In addition Simpson mentioned that the sphincter disturbance described by O'Connor was also a part of the toxicology of ephedrine.

Sargant and Blackburn (1936) investigated the effect of benzedrine on the intelligence test scores of a large group of patients at the Maudsley Hospital with successful results. No ill effects of their experiments are recorded, except in the case of a young man suffering from a depressive state with anxiety features. He complained of very unpleasant subjective symptoms, an increase of palpitation, and sweating, yet actually he showed a large rise on retesting.

In a recent annotation (1937) the *Lancet* refers to the investigation of Davidoff and Reifenstein (1936), who reported the effects of a ten to fourteen days' course of benzedrine on normal subjects, and on several groups of psychotic patients. The manifestations observed both subjectively and objectively were extraordinarily numerous and varied. Five of the ten normal subjects developed a state of irritable restlessness which they did not relish, and from the case reports it was evident that the increase of activity and efficiency sometimes involved a dangerous degree of disrespectfulness to superior officers on telephones. Solomon, Mitchell, and Prinzmetal (1937) have produced a fair case for its beneficial effect in post-encephalitic Parkinsonism. They found, by contrast, that the drug was of no use in arteriosclerotic Parkinsonism or in psychotic patients with continuous asthenia, and out of their large experience they join other authors in giving warnings against its indiscriminate use. The *Lancet* infers that caution is clearly advisable, especially in the administration of the drug to normal or relatively normal people, as distinct from those with chronic or incurable disorders.

Case Report

The patient was a robust young man of 26 who had previously enjoyed good health and had suffered from no important illness. He was a pharmaceutical student, and was preparing for the final examination. He had seen articles in the lay press on the action of benzedrine, and learnt that the drug was recommended in the medical press for its stimulant effect on the nervous system, and in particular that it had been found valuable in preparation for examinations. A bottle containing fifty tablets of benzedrine, each containing 10 mg. of the drug, was obtained from a local chemist. From June 15 to 20 last he took two tablets each day, and at first felt no ill effects. On the contrary, he had a marked feeling of well-being and was mentally more efficient, and was more talkative for the first three days. Afterwards he experienced some dryness of the mouth, thirst, and occasional headaches. He worked hard on these days, and remained up until 2 a.m.; sleep afterwards was light, and he awoke easily at 7 a.m., his usual hour. On June 19 he was noticed to be pale, which was attributed to hard study; his colour was usually very good.

The written portion of his examination was held in Cardiff on June 22, 23, and 24, and on each of these days he took only one tablet after breakfast, as he had to travel in daily from a distant country town. Throughout the first part of the examination he had "throbbing headaches" to such an extent that his papers "suffered badly." At this time no

suspicion of any harmful effect from the benzedrine occurred to him. No tablets were taken from June 25 to 28, and sleep even on these days was very restless. On each of the following four days one tablet was taken, and he travelled to London on June 30 for the practical part of the examination, which lasted three days. Severe headaches were again felt daily, and sleep was poor and restless. He returned home by a night train in the early morning of July 3 and, despite a feeling of utter weariness, was unable to sleep during the journey of six hours. At home he was observed to be very pale, and he complained of severe headache and giddiness, thirst, and a dry mouth. Although feeling thoroughly exhausted he was fully awake and unable to sleep.

In the early afternoon of the same day palpitation and a feeling of faintness supervened. He was given a small amount of brandy, when he improved and dozed for a few hours. He became restless again and began to vomit, and suddenly collapsed. The patient was seen at once by Dr. Milne, who found him unconscious and in a severe state of collapse. The pulse was extremely weak, rapid, and irregular, the pupils were dilated, and the skin was cold and moist: he was critically ill for one hour. Vomiting was profuse and of a projectile character for about thirty minutes. He responded fairly quickly to the usual measures of stimulation. Sleeplessness and restlessness were severe for the following three days, despite the use of simple sedatives. Gradual and continuous recovery then ensued, and he is now almost well again. There was no diarrhoea, and constipation was troublesome during the worst stage of his illness. Micturition was normal, except for being more frequent as a result of taking increased fluid for thirst. No haemorrhages occurred throughout the whole course of the illness.

Blood films were examined by Dr. Phillips on July 5 and a slight anisocytosis was the only qualitative change, apart from the poverty of the red cells in haemoglobin.

I saw him in consultation on July 9 and found him to be well nourished but very pale. No retinal or cutaneous haemorrhages were present, and no jaundice. There was slight general enlargement of the heart and fairly natural sounds, except for a haemic bruit in the pulmonary area. The pulse rate was 84, with regular rhythm; and the blood pressure 124 mm. Hg systolic and 50 mm. diastolic. The other systems were healthy, and the liver and spleen not palpable. The urine was normal. Unfortunately, a complete blood examination was impossible on that day. The haemoglobin, however, was 40 per cent., and some films showed much the same qualitative change as in the previous examination. The appearance of the patient corresponded with a red cell count of about two millions.

A full blood count was made a week later, when he was found to have improved in health as a result of the administration of full doses of ferri et ammon. cit. The result was as follows: Red blood corpuscles, 3,080,000 per c.mm.; haemoglobin, 56 per cent.; colour index, 0.9; white blood corpuscles, 5,400 per c.mm. The qualitative change was a little more marked than at my previous examination, and many of the red blood cells now showed polychromasia. No nucleated forms were seen, but there were a few myelocytes.

I saw him again on August 1, when he had improved still further. He was much less pale, and said that he felt almost well again. He was free from headaches, and sleep was good.

Another blood count was now done, with this result: Red blood corpuscles, 4,940,000 per c.mm.; haemoglobin, 94 per cent.; colour index, 0.9; white blood corpuscles, 6,800 per c.mm. The red blood cells were well stained and showed only slight variation in size. No polychromatic staining was seen. The white blood cells were present in normal proportions, but there were no abnormal cells.

Conclusion

A case of acute aplastic anaemia following the self-administration of benzedrine is described. The total amount taken was 190 mg. in the course of nineteen days. Severe cardiovascular collapse occurred the day after the last dose was taken. Gradual recovery ensued, with restoration to normal health. The patient told me that the drug was being rather much used by students preparing for examinations. It is evident that the sale of this drug should now be strictly controlled by including it in the Schedule of Poisons.

I am much indebted to Drs. R. Baird Milne and Robert J. Phillips for their help in preparing this report.

PERNICIOUS ANAEMIA WITH DIABETES MELLITUS

BY

H. G. McGREGOR, M.D., M.R.C.P.

Medical Registrar, Royal Sussex County Hospital

Though the combination of diabetes and pernicious anaemia is well recognized it is sufficiently unusual to merit study. The following case reports are illustrative.

Case I

A carpenter and joiner, aged 43, was known to suffer from pernicious anaemia with achlorhydria. He first came to hospital in July, 1936, when his blood count showed: haemoglobin, 52 per cent.; red cells, 1,900,000 per c.mm.; colour index, 1.3; white cells, 4,900; and a normal differential count. He was given pernaemon forte 4 c.cm. each fortnight and was making satisfactory progress, his blood count in February, 1937, being: haemoglobin, 95 per cent.; red cells, 4,800,000 per c.mm.; colour index, 1. For eighteen months he had been complaining of paraesthesiae of the feet, but there was no weakness, and no physical signs of cord involvement had ever been elicited. The urine had always been normal.

He was one of a family of seven, five of whom were alive and well. One sister had been admitted to hospital three months previously suffering from simple achlorhydric anaemia. Her blood count on admission was: haemoglobin, 25 per cent.; red cells, 1,600,000 per c.mm.; colour index, 0.8; white cells, 9,300; normal differential count. The gastric contents showed complete achlorhydria both to fractional and to histamine test meals, and the Wassermann reaction was negative. She was treated with blood transfusion and massive doses of iron, and was discharged, greatly improved, after three months' treatment, when the blood count was: haemoglobin, 75 per cent.; red cells, 5,000,000 per c.mm.; colour index, 0.75; white cells and differential count normal. The father had died at the age of 69 from heart trouble and dropsy; the mother was alive, aged 74, and suffered from simple goitre.

On March 16 the patient reported at the out-patient department complaining of the sudden onset of thirst and polyuria ten days previously. During this short period he had become very weak, had noticed increasing dyspnoea and giddiness on exertion, and had lost considerable weight. He was unable to eat owing to the dryness of his mouth, in spite of the fact that he was very hungry, and had found that his vision was becoming misty and his voice husky. On examination he looked ill and dazed, and he staggered slightly when walking. His temperature was 98.4° and his pulse rate 60. The physical examination was negative. There was no smell of acetone in the breath, but the urine was loaded with sugar and ketone bodies.

On admission to the ward his urine was found to contain 12 per cent. of sugar, his blood sugar was 716 mg. per 100 c.cm. (his last meal having been two hours previously), and his blood count was: haemoglobin, 80 per cent.; red cells, 3,500,000 per c.mm.; colour index, 1.4.

During the first twenty-four hours in hospital he received 240 units of insulin and 240 grammes of glucose. Thereafter he was treated with a diet containing 140 grammes of carbohydrate and 50 units of insulin daily; he also received 2 c.cm. of campolin every other day. Subsequently it was found possible to reduce the daily amount of insulin in a step-like manner until six weeks later his urine remained sugar- and acetone-free without insulin, and his sugar tolerance was within normal limits. He was discharged on May 4 with a blood count of: haemoglobin, 82 per cent.; red cells, 3,960,000 per c.mm.; colour index, 1.03. He was feeling remarkably well, and had put on one stone in weight.

While he was in hospital it was found that the gastric contents contained no free hydrochloric acid during a histamine test meal. Blood examination showed a sedimentation rate of 27 mm. in one hour (Wintrobe's method); haematocrit test 40 per cent.; corrected sedimentation rate 19 mm.; cell volume index 1.06; plasma cholesterol 164 mg. per 100 c.cm.; Wassermann reaction negative. The increased sedimentation rate remained unexplained.

The second case is less clear-cut, in that the condition of the patient whilst in hospital provided no opportunity for performing a test meal. The presence of achlorhydria, therefore, was never proved. Nor was any family history available. There are, however, enough facts to make the case worth recording if only to illustrate the onset of the diseases in the reverse order.

Case II

A retired nurse, aged 70, was known to have been a mild diabetic for at least a year. She had been in the habit of taking 20 units of insulin by injection night and morning, and of living on a slightly reduced carbohydrate diet. On this regime she had maintained comparatively good health, and her urine had only occasionally shown slight reduction of Benedict's solution.

On October 3, 1932, she was admitted to hospital complaining of increasing pallor, glycosuria, and thirst during the previous three weeks. She looked ill, and was dull and drowsy. Her mucous membranes were pale, her pulse 100 and weak, and her respirations rapid. A blood count showed: haemoglobin, 34 per cent.; red cells, 1,480,000 per c.mm.; colour index, 1.2; white cells, 3,600; and a normal differential count. The red cells showed anisocytosis and poikilocytosis, and both normoblasts and megaloblasts were seen. The average diameter of red cells by Pijper's method was 8.6 μ, and the Price-Jones curve showed the typical shift to the right. The blood sugar was 500 mg. per 100 c.cm.; the urine contained 3 per cent. of sugar and much diacetic acid.

During the twenty-four hours following her admission she received in all 170 units of insulin and 170 grammes of sugar. She was taking fluids and passing urine well, and looked and felt better. Considerable difficulty was experienced in stabilizing her diabetes, and her blood sugar varied rapidly between 60 and 370 mg. per 100 c.cm. During the next fourteen days, however, she was given 30 units of insulin daily, and her general condition improved considerably.

Shortly after admission she received a blood transfusion of 100 c.cm. and half a pint of gum saline intravenously, and thereafter one tube of liver extract and one phial of ventriculin were given daily. Three weeks after her admission her blood count was: haemoglobin, 40 per cent.; red cells, 1,315,000 per c.mm.; colour index, 1.5; and white cells 9,400.

Twenty-three days after admission she suddenly became ill with pulmonary congestion and died a few hours later.

Discussion

That diabetes and pernicious anaemia are sometimes found in association has often been remarked, and inquiry into the subject covers a period of twenty-six years. The best reviews of published cases are by Root in 1931 and again in 1933, and by Watson in 1933. Since then, however, few authors have written about it—Benjamin in 1934, Jolliffe, Brandaleone, and Most in 1935, and one or two more.

The first published report was by Parkinson as recently as 1910. He described the case of a man, aged 49, with pernicious anaemia who developed glycosuria, ketosis, and coma, terminating in death. At necropsy the characteristic findings of pernicious anaemia were disclosed. The pancreas was normal macroscopically and microscopically. Chvostek in 1918 was the next to describe a patient with both conditions, and in 1923 Giffen and Bowler alluded to two more in a paper reviewing the diseases that might be associated with pernicious anaemia. Two further cases were reported by Adams in 1925.

In 1931 Root made the first collection, which consisted of forty-eight cases: other reports followed, and in 1933 he collected another series of thirty-one. In the same year Watson added three more case histories and published an excellent review with a summary of the literature, and it is probable that at the time of the publication of this paper the total number of cases of combined diabetes and pernicious anaemia on record was seventy-nine.

That two so entirely different conditions should often be found in association is most remarkable, and frequent attempts have been made to discover a relation between them. The task, however, has not been easy, partly because of the difficulty of deciding which is the primary disease and which the complicating one, and partly because the incidence of the combination varies in different series of cases of diabetes and pernicious anaemia. There are, however, certain conditions common to both which might predispose to their simultaneous occurrence; and certain facts are known about alterations in carbohydrate metabolism in anaemic states which must also be taken into consideration.

The Primary Disease and the Complicating Disease

A point about which there is no clarity is whether the diabetes should be considered as a complication of the anaemia or vice versa. In Case I above the pernicious anaemia was known to have preceded the diabetes; in Case II it was probably the reverse; and in the majority of reported cases it was the diabetes that developed first. In two of Watson's cases the time of onset of the pernicious anaemia could not be stated with certainty as paraesthesiae were noted in the history before anaemia was suspected, and mild anaemia might have been present before the diabetes developed or before either disease was discovered. In one at least of Root's cases achlorhydria was found before any sign of anaemia.

Frequency

Some idea of the frequency of the association can be gained from various writers, but it varies in different series.

1. Watson found that in 949 diabetic patients of 25 years of age and over admitted to the Deaconess Hospital during the twelve months ending June 1, 1932, ten cases of pernicious anaemia occurred (1.05 per cent.).

2. Murphy and Moxon in 827 diabetics saw three cases of pernicious anaemia (0.36 per cent.).

3. In 370 cases of pernicious anaemia Wilkinson had four diabetics (1.05 per cent.).

4. The association was found in fifteen in a combined series of 2,461 patients with pernicious anaemia (0.61 per cent.) (Adams, Giffen and Bowler, Goudsmit, Joslin, Murphy and Moxon, Wright, and Wilkinson).

These figures are certainly suggestive of something more than chance, but no more than suggestive.

Factors Predisposing to Combined Incidence

Root has indicated some factors which may predispose to a more frequent combined incidence.

1. Achlorhydria is of fundamental significance in pernicious anaemia and often occurs in diabetes. The latter fact is perhaps not fully appreciated, but according to evidence adduced by Bowen and Aaron, Curtis, Ingram, Mason, Rabinowitch *et al.*, and Wohl, diminished or absent gastric hydrochloric acid occurs in 30 to 40 per cent. of diabetics. Hartfall found three diabetics among 336 cases of achlorhydria. This might prove to be a common aetiological basis.

2. The longer duration of life brought about by improved treatment might render a sufferer from one disease more likely to contract the other. It appears that the tendency to the development of defective gastric secretion increases with the duration of the diabetes and with the age of the patient. Since, moreover, the diabetes antedates the pernicious anaemia in most of the cases there appears to be some justification for regarding diabetics, in virtue of their prolonged existence, as more prone to develop pernicious anaemia.

3. The age factor.—No case has been observed in a young person. All occurred during the age period which is usual for the onset of pernicious anaemia and which includes the age most common for the development of diabetes.

4. *Hereditary tendencies.—The* familial tendency is well recognized in both diseases, and in one of the above reports the occurrence of a sister with achlorhydria and microcytic anaemia is a case in point.

Though these factors are common to both diseases, especially where diabetes is the primary condition, there still remain those cases where pernicious anaemia was the first to develop. In the latter circumstance certain changes in carbohydrate metabolism that are known to occur in anaemia seem more likely to be the agents which lead to the double pathology.

Conditions Favouring Development of Diabetes in Pernicious Anaemia

Davidson and Gulland, for instance, found some evidence that the achlorhydric stomach of pernicious anaemia empties rapidly, and in 1929 MacCullum suggested a hormone in the intestinal mucosa, formed under the stimulus of sugar, which controls the secretion of insulin. Since pernicious anaemia is a deficiency disease, other deficiencies of this nature possibly coexist.

Again, disturbance of sugar metabolism has many times been reported as a result of anaemia. As early as 1877 Claude Bernard produced hyperglycaemia in dogs by repeated bleedings. Strauss reported an increased excretion of sugar in diabetics following venesection. Isaac and Hendrick found the blood sugar raised in pernicious anaemia, and Johnsson thought that the height of the blood sugar was related to the severity of the anaemia. In the same year, however, Blumenthal and Neuburger could find no definitely characteristic change and no connexion between the severity of the anaemia and the blood-sugar level. If it is true that changes in sugar metabolism of this nature occur as a result of anaemia, then it is quite conceivable that this fact has some bearing on the question of diabetes complicating pernicious anaemia. But a criticism that immediately comes to mind is that there is no evidence that the diabetes in all these cases developed during an anaemic phase. It certainly did not in the one reported above.

Finally, in 1929 Bloiner and Murphy announced a blood-sugar-lowering effect following the oral administration of liver, though here again there has been no confirmation by other workers. Recently, however, Jolliffe, Brandaleone, and Most have reported changes in carbohydrate tolerance produced by high protein diets in two cases with the combined diseases.

Evidence, therefore, is contradictory, and no adequate explanation has yet been offered regarding on the one hand the mechanism of production of high blood sugar and abnormal sugar tolerance in pernicious anaemia, nor on the other the occasional occurrence of pernicious anaemia complicating diabetes. It is true that there is a certain amount of common ground between them, yet it appears that the only rational attitude is the one adopted by most authors—namely, that the phenomenon is a chance combination.

Summary

1. Two cases of combined pernicious anaemia and diabetes mellitus are described.

2. The history of knowledge concerning this association of diseases is given and the theories that have been put forward in explanation are discussed.

3. From a study of the literature no actual proof of aetiological relation is available.

My thanks are due to Dr. E. Rivaz Hunt, Dr. G. Lyon Smith, and Dr. E. D. Scott for permission to publish notes on the above cases.

Clinical Memoranda

A Case of Pubertas Praecox

The extreme rarity of this condition and the scantiness of the literature on the subject have led to its frequent confusion with adrenal virilism or pseudo-hermaphroditism.

The patient is a girl aged 6 years 10 months. She is the first of a family of three. The mother was quite well during pregnancy, but the labour was prolonged and forceps had to be used. The birth weight was 10 lb. The child had pneumonia at 3 years, followed by otitis media. Paracentesis of both drums was performed. Since then she has had otorrhoea on and off. There have been no other childish diseases. The family history shows nothing abnormal. Her sister is 4½ years and her brother 3½ years old; both are normal.

The child's progress since birth has been precocious. The first tooth erupted at 4 months; she walked quite well at 11 months, and looked like a child of 3 years at 18 months. Her appetite has always been voracious. At 3½ years of age she began to menstruate. Menstruation occurred four times in a year, each time lasting one or two days. There was no dysmenorrhoea. There was no menstrual period between 4½ and 5½ years of age, but menstruation occurred again at 5 years 9 months. Another year passed before the next period at 6 years 9 months. This time it lasted three days, with headache and some lower abdominal pain.

The child has been under observation for the past fifteen months, and during that period she has suffered from several attacks of pyrexia up to 103° F., which were attributed to a chill. There has been headache during these attacks, but no vomiting. Headache has been a feature of the case, especially when the child indulges in strenuous exercise—for example, drill at school.

PHYSICAL EXAMINATION

Her appearance is that of a well-developed girl of 12 to 14 years. There is marked premature development of the feminine form, with enlargement of the mammary glands, female configuration of the hips, prominence of the mons veneris, on which there is some fine dark hair. The external genitals are of the female type with no enlargement of the clitoris. The abdomen protrudes and there is some lordosis.

The following are some of her measurements: Height, 53¾ inches—that is, she is eleven inches taller than a normal child of her age. Weight, 74 lb. (26 lb. heavier than the normal child). Head, 21 inches; chest (over the breasts), 26¼ inches; abdomen, 24 inches; and hips (over greater trochanters), 28½ inches. The child has gained 2½ inches in height and 10 lb. in weight during the last fifteen months.

Examination showed the following results: Heart, normal, blood pressure, 115/60; central nervous system, normal; eye movement normal in all directions; optic disks, normal. The liver, spleen, and kidneys were not palpable, and there was no appreciable disease. The cervix uteri is well developed and the uterus, on bimanual examination, was found to be almost adult size. No enlargement of the uterine appendages could be detected. The urine, which was acid, had a specific gravity of 1015 and contained no albumin or sugar. The skull was radiographed with especial reference to the pineal gland, but proved normal.

There is nothing very remarkable in her personality, except that her ideas are rather more mature than those of a child of her age. Her mental age is normal: there is certainly no evidence of retarded mental function.

DISCUSSION

It might not be out of place here to make a few remarks on the factors differentiating this condition from adrenal virilism. In adrenal virilism occurring in girls before puberty the configuration of the body approaches the male type: the voice deepens, hirsuties is a feature of the disease, and the hair is of male distribution. The external genital organs show precocious development with marked hypertrophy of the clitoris. The uterus is not enlarged and there is no menstrual bleeding. The mammary glands are not developed—in fact, failure of their development is more usual.

The most likely diagnosis in this case would be pineal syndrome due to neoplasm or hyperplasia of the pineal gland.

Southampton.

Agranulocytic Angina following Bismuth Injections in a Case of Syphilis

The interesting features of this case, which closely resembles reported cases of agranulocytosis, are its association with bismuth (only 8 grains in all were given) which in itself has a tendency to produce stomatitis, and possibly with syphilis. The absence, however, of any blue pigmentation in the mouth, of casts, or of any appreciable amount of albumin in the urine, and the sudden onset of the condition, differentiate the case from one of simple bismuth poisoning, of which I have seen several instances, but it suggests that perhaps bismuth may be able to precipitate agranulocytosis in the same way as does amidopyrine, which was not a factor in this case.

CASE REPORT

The patient, a native male adult employed on the Roan Antelope Copper Mine, was admitted to hospital on account of infective syphilis, having a primary chancre with a 4 plus Kahn reaction. His urine and gums, examined before treatment began, were normal, and he was otherwise healthy.

On January 16, 1936, 10 minims of bismostab (Boots), containing 2 grains of metallic bismuth in suspension, were injected into the muscles of the buttocks, the bottle of bismostab being well shaken up before drawing off the dose, and a needle first inserted alone into the muscle to avoid the possibility of injecting into the vein. The same dose was injected similarly at weekly intervals for three weeks, no additional treatment being given. Urine taken at the time of the last injection, February 7, was normal, and the gums then showed no trace of pigmentation or ulceration.

His temperature, which for the four previous weeks had not risen above normal, suddenly rose on February 12 to 105° F., and was maintained between 100° and 105° F. till his death. At the onset he complained only of a sore throat and a dry cough, and on examination showed some enlargement of the tonsils with slight general injection of the pharynx. A relative lymphocytosis was noted in a blood smear taken at this time

On the 14th small superficial ulcers were observed along the outer margin of the right gums with no associated hyperaemia, and after a further two days these had developed into extensive yellowish-white sloughs. No pigmentation was present and there was still no hyperaemia. A blood examination now revealed a complete absence of neutrophils and eosinophils. The haemoglobin was 81 per cent., the colour index 0.96, and the erythrocytes 4,290,000 per c.mm. The leucocytes numbered 3,800 per c.mm., 83 per cent. being lymphocytes and 17 per cent. monocytes. His urine was acid, with a specific gravity of 1026, and contained only a trace of albumin.

The following day, February 17, the sloughs were more extensive and the patient's general condition worse; his tongue was coated with a dry brown fur, and a marked icteric tinting of the conjunctiva was noted. A blood count now showed: haemoglobin 70 per cent.; colour index 0.97; erythrocytes 3,600,000—some anisocytosis present; leucocytes 2,200 per c.mm. (monocytes 21 per cent. and lymphocytes 79 per cent.). Neutrophils and eosinophils were still absent. On February 18 a few neutrophils (stab forms) and eosinophils appeared in the blood. The haemoglobin was 70 per cent., the colour index 1.0, and the erythrocytes 3,560,000 per c.mm. The leucocytes numbered 2,300 per c.mm., and consisted of neutrophils (stab form) 1 per cent., eosinophils 1 per cent., monocytes 18 per cent., and lymphocytes 80 per cent.

The patient died on February 20, eight days after the onset of his illness. A post-mortem examination showed marked pallor of the bone marrow at the ends of the tibia and femur. The liver and spleen were enlarged, but firm and of normal appearance on cutting. This enlargement was probably due to chronic malaria. The remaining organs appeared normal apart from a yellow coloration due to the jaundice.

No specific treatment had been used in this case, as no nucleic acid preparation was obtainable locally, and the patient died before any could be procured. Mouth washes of potassium chlorate and carbolic acid and, later, swabbing of the gums with hydrogen peroxide were employed, along with a daily saline aperient.

I should like to express my gratitude to Mr. R. B. English of Luanshya for laboratory investigations, the most important feature in the diagnosis.

J. H. DOWDS, M.B., B.Ch., M.Sc.,
N. Rhodesia. Medical Department, Luanshya.

Skin Diphtheria Associated with Clinical Diphtheria and Scarlet Fever

I think that the case recorded below may have some interest from the point of view of both clinical and preventive medicine.

CLINICAL RECORD

Two little boys contracted scarlet fever and were sent to hospital. Four days after they had been allowed home their father reported that two other children were ill, and that one of them had a rash. These children also were found to have scarlet fever, and were sent to hospital. The father complained casually that he himself had sore throat, headache, and loss of appetite, and had not been able to sleep. When examined he had a circular patch of membrane on an inflamed tonsil, a temperature of 100°, and a pulse of 120. He was sent to bed and a dry swab was taken. The membrane was loosely adherent, and there were no bleeding spots where it had been detached by the swab. Serum was at first withheld pending the result of examination of the swab. Next day, however, the membrane had re-formed and had spread to the opposite tonsil and involved the uvula. The patient felt and looked much more ill, and 12,000 units of antitoxin were given intramuscularly. The following day the throat had cleared up considerably, and the patient was much improved, having had a comfortable night.

One of the children who had been discharged after scarlet-fever was noticed to have a moist dermatitis at the back of the ear, and further search revealed a similar patch in the axilla. A dry swab was taken from the axilla, and a report asked for as to the existence of diphtheria bacilli and for haemolytic streptococci.

BACTERIOLOGICAL REPORT

The reports on the swabs were as follows:

Child's Axilla.—Bacilli similar to *B. diphtheriae*, both in morphological and in staining properties, were observed. A few isolated cocci were also present.

Father's Throat.—Organisms similar to *B. diphtheriae* in morphology were present in culture from this swab. Some of their staining characteristics were not quite typical, but they must be regarded with suspicion. A blood-agar plate culture showed numerous streptococci of the α-haemolytic type, but only an occasional β-haemolytic colony. Scarlet fever streptococci conform to the latter type in appearance, but one would have expected a much higher yield of these organisms from a clinical case of scarlet fever.

COMMENTARY

In view of the clinical behaviour of the case and the speedy response to serum treatment there would appear to be no reasonable doubt but that the case was one of diphtheria.

Skin diphtheria has been reported occasionally, but its occurrence does not seem to have attracted the notice it deserves. Over twenty years ago Dr. J. D. Rolleston (1916) recorded the case of a boy with multiple whitlows which had existed for over two months but which healed within a week after a positive swab had been found and serum given. Dr. C. O. Stallybrass (1936), influenced, he says, by observation of Professor Bu's findings in Copenhagen, suggested that school doctors and skin specialists should take swabs at random in cases of "*impetigo*" and facial "eczema," and the result was that "we were rewarded by a plentiful crop of cases of nasal diphtheria."

Damon in 1934 reported a case of pustular eruption on the face, which spread rapidly to chin and forehead and resembled impetigo. The temperature varied from 99.8° to 101° F. and the pulse from 108 to 130. A pure culture of diphtheria bacilli of a virulent type was found. The patient improved and got well immediately antitoxin was given. It is noteworthy that Damon reports that no bacilli could be isolated from the throat or posterior nares although repeated cultures were made.

It may well be that those epidemics of impetigo (1914) with a high mortality reported at times were in reality outbreaks of skin diphtheria. That only streptococci and staphylococci were isolated hardly excludes the possibility of diphtheria in view of the very diverse experiences of the value of the swab in diagnosis. In this connexion readers will recall a prolonged discussion on the swab in the columns of this *Journal* about two years ago.

It is of interest to note that the skin lesion now reported cleared up rapidly on the application of ung. hydrarg. nit. dil.—one of the commonest ointments used in impetigo.

The part played by skin diphtheria in producing adult and herd immunity, and in starting epidemics of diphtheria, may be worthy of further study.

Reviews

ENCYCLOPAEDIA OF MEDICAL PRACTICE VOL. IV

The British Encyclopaedia of Medical Practice, including Medicine, Surgery, Obstetrics, Gynaecology, and other Subjects. Volume 4, *Diarrhoea to Endoscopy of the Rectum.* Under the general Editorship of Sir Humphry Rolleston, Bt., G.C.V.O., M.D. (Pp. 600; illustrated. 35s. net.) London: Butterworth and Co. (Publishers), Ltd. 1937.

The volumes of the new Encyclopaedia of British medicine continue to appear at regular intervals, the fourth one of the series, now before us, covering the subjects diarrhoea–endoscopy. Prominent among these is the consideration of dislocations, fractures, and associated injuries admirably set out for the help of the general practitioner by Professor G. R. Girdlestone. Since the war, deriving from the multiple injuries of gunshot wounds and the subsequent experience with road accidents, the modern technique in the treatment of fractures has reached a high standard. Professor Girdlestone approaches the subject by a brief reference to first aid, discusses the general principles of diagnosis, reduction and fixation apparatus, and then deals regionally with particular fractures and dislocations. From the standpoint of efficiency there is much to be said for getting the patient as soon as possible to a hospital with a fracture service, but the practitioner who is called in to render first aid in case of accident must undertake not only the support of the patient but must be trained to deal with the situation so as to minimize further damage to tissues and to place the injured part in such a position as rapidly to facilitate repair. In a compact discussion of the subject Professor Girdlestone has in seventy pages managed to get in the essentials, and this section should be most helpful.

Among the disorders of digestion dealt with are the general causes and clinical aspects of diarrhoea by Sir Arthur Hurst, diarrhoea occurring in infancy and childhood by Dr. R. W. B. Ellis, and tropical forms of diarrhoea associated with flagellate infections and so-called hill diarrhoea by Dr. Hamilton Fairley. The aetiology of infantile summer diarrhoea in England appears still to be obscure. An infective organism has been demonstrated in far fewer cases than in the United States, on the Continent, or in Australia, and physicians are led to postulate environmental, dietetic, or allergic states. It should be possible to differentiate further the clinical aspects of these groups, so that indications for treatment may be more readily set out. Approaching the subject from the other side, Major-General Perry and Lieut.-Colonel Biggam are on more solid ground in dealing with the aetiology of bacillary dysentery. Here the bacteriology has largely been worked out, and the clinical aspects of the various groups are becoming differentiated. There are, however, still considerable difficulties in producing specific sera for therapy, except in the case of the Shiga bacillus, for which an effective antitoxin can be prepared. A full treatment of the subject of diverticulosis and diverticulitis of the colon by Sir Edmund Spriggs and Mr. O. A. Marxer, an introduction to dyspepsia by Dr. Robert Hutchison, and a discussion of the special characters of carbohydrate intestinal dyspepsia by Sir Arthur Hurst complete a highly instructive series of articles on disorders of digestion.

Dr. Comrie introduces the subject of diet in treatment with a general statement of the food requirements of the body under physiological conditions, and discusses the various systems of diet advocated or adopted. These subjects are so much talked of by patients that practitioners will be grateful for the succinct accounts of diets and the indications for their use, together with material for refuting false or exaggerated claims. In a scholarly article Dr. Helen Mackay brings forward the main facts of diseases due to dietetic deficiency. Throughout the world dietetic deficiencies are prevalent, mostly from necessity but sometimes through ignorance. Certain deficiencies are known to be common in British diets, iron, for instance, and probably often calcium, phosphorus, and vitamin D in many parts of the community. Besides gross disease due to deficiency there is probably much disability or ill-health obscurely brought about in this way.

An interesting series deals with electricity and medicine. Dr. Cumberbatch discusses electrodiagnosis, and the special form of treatment with diathermy; and Dr. Heald electrotherapy in general. Emphysema of the lungs and empyema by Dr. R. V. Christie and Mr. Tudor Edwards respectively represent the medical and surgical aspects of respiratory disease in this volume, while Dr. Christie also writes a good study of dyspnoea. Other disabilities are dysphagia and dysphonia from the pen of Mr. Lionel Colledge, who contributes the section on ear diseases; dysmenorrhoea and dyspareunia by Mr. Eardley Holland, whose understanding articles will be very helpful to practitioners so often called to deal with these matters; while the clinical aspects of drug eruptions will be less puzzling when Dr. R. T. Brain's contribution to the subject is studied. Nervous diseases include disseminated sclerosis by Drs. F. M. R. Walshe and J. G. Greenfield, diplopia by Mr. P. G. Doyne, and encephalomyelitis and epidemic encephalitis by Dr. W. G. Wyllie.

Dr. Gardiner Hill's account of dwarfism and infantilism is well documented and up to date, and the disorders of the uterine mucous membrane are discussed from the pathological and clinical aspects by Professor M. J. Stewart and Drs. A. M. Claye and James Young. Other articles contribute to a very useful volume. The editing and printing are praiseworthy, but a comparison of radiographs would point to the desirability, for clarity and precision, of using special paper.

CHRONIC RHEUMATISM

Chronic Rheumatic Diseases. Edited by C. W. Buckley, M.D., F.R.C.P. Being the third Annual Report of the British Committee on Chronic Rheumatic Diseases appointed by the Royal College of Physicians. No. 3. (Pp. 142. 10s. 6d. net.) London: H. K. Lewis and Co. 1937.

The third volume of the Reports on Chronic Rheumatic Diseases is welcome, for, as Professor Fraser says in the foreword, this and the first two volumes offer the student as complete a survey of recent work on chronic rheumatism as he is likely to find anywhere. In the opening article Professor Okell throws grave doubt on the fundamental justification for vaccine therapy in these diseases—a view that may be regarded as unduly pessimistic by some but is a seasonable corrective to those who are wont to regard the rheumatic patient as a never sufficiently filled receptacle for injections. Professor Learmonth writes a review of recent work on sympathectomy in rheumatoid arthritis, and points out that in carefully selected cases it may be a useful symptomatic measure for the relief of pain but that it should never be regarded as in any sense a specific remedy for the disease.

Kahlmeter gives a most useful review of his own and others' experience of *x*-ray therapy and thinks highly of its use, especially in gonorrhoeal and septic arthritis, in bursitis, and tendinitis. Race gives a valuable survey of the theories advanced as to deficiency of vitamins as a causative agency in arthritis. In the rheumatoid type a deficiency of A and C and possibly of B_2 is not uncommon, but whether this deficiency is causal or not still remains non-proven. Collins describes two unusual cases of rheumatoid arthritis with a neutrophil leucopenia and enlargement of the liver and spleen, and discusses them in relation to the leucocyte counts commonly met with in chronic rheumatism.

Several critical reviews are given of recent work, of which the most valuable is that on chrysotherapy. There can be no doubt that gold properly administered is a promising and useful remedy, but still greater trial is necessary to clarify the correct dosage and suitable selection of cases, while it is obvious that this is a very dangerous weapon in inexperienced hands. Hench supplies a long review, with a full bibliography of American literature on arthritis. The most interesting feature of this is the work on pyrexial treatment of gonorrhoeal arthritis, which seems almost specific in the early stages and helpful even in later stages. Jennings draws attention to the neglected use of sodium salicylate in the treatment of gout, especially in the interval periods, when it rivals cinchophen in the power of increasing the elimination of uric acid and is much less dangerous. Finally, abstracts and reviews of the principal Continental literature of the year are supplied by Drs. Bach and Pether.

It may be complained that there is nothing very original in this report, but Sir Humphry Rolleston and his committee deserve congratulations on keeping those who are interested fully abreast of all that is happening in the domain of chronic rheumatism.

THE PSYCHOTHERAPY OF NEUROSIS

The Common Neuroses. Their Treatment by Psychotherapy. An Introduction to Psychological Treatment for Students and Practitioners. By T. A. Ross, M.D., F.R.C.P. Second edition. (Pp. 236. 10s. 6d. net.) London: E. Arnold and Co. 1937.

Dr. Ross brought out the first edition of this valuable textbook at a time when psychotherapy was comparatively little known in this country.[1] The second edition has appeared in response to a demand by the hundreds of medical men and women who have now undertaken or are undertaking this difficult and elusive work for some sort of guide to its perplexities. Seventeen years ago the author wrote in his preface that in his opinion most patients suffering from neurosis could be treated by general practitioners. It is very interesting to read that he has found no reason to change his mind. He points out, however, a fact of which no general practitioner should ever lose sight: that there is a residue which the general practitioner would be well advised not to touch. Most neurotics, he says, are not difficult to cure, but some may be made very much worse. He has therefore attempted to describe the cases which the general practitioner ought to leave alone, but urges him to contribute his share of psychotherapeutic treatment to a world which is being progressively invaded by neurosis. He has left out his original chapter on the application of the Freudian method, feeling that this subject can only be properly dealt with by a Freudian. The views Dr. Ross expressed in his first edition remain substantially the same, but he has added many examples which illustrate principles.

BONE PRODUCTION AND BONE GROWTH

The Role of Chemiotaxis in Bone Growth. By A. P. Bertwistle, M.B., Ch.B., F.R.C.S.Ed. (Pp. 59; 32 illustrations. 8s. 6d. net.) London: Henry Kimpton. 1937.

Bone production and bone growth are fascinating problems which have aroused much interest recently, and so this monograph cannot but attract attention. The author states that the object of the book is "to describe disruptive chemiotaxis, a new process to Medicine, and to lay down a law which, based on histological grounds, will be found to cover the whole field of bone pathology, viz.:—that whenever young fibrous tissue, particularly young blood vessels, come into contact with bone or a calcified deposit, new bone formation occurs." Disruptive chemiotaxis, he tells us, is a term coined to express the power of certain hard substances of attracting and drawing into themselves certain soft, living structures. We do not feel that we can congratulate the coiner on this addition to an overburdened nomenclature, while we search in vain for some new insight into the nature of the process whereby developing structures follow particular pathways in relation to their environment.

Mr. Bertwistle's little book consists of six chapters, a bibliography of some seventy-five references, and an index. It is illustrated by thirty-two figures, the majority of which are from prints of *x*-ray photographs. These are for the most part clear and well reproduced. Fig. 24, described as periosteal sarcoma, in a recent work such as this might in conformity with modern surgical pathological nomenclature be better designated osteogenic sarcoma, while some would also have preferred to see the term myeloma (p. 33) replaced by osteoclastoma. The manufacturers of "elastoplast" will be pleased to note the statement on page 32.

A real advance in our knowledge of bone pathology was made when Leriche and other observers emphasized the fact that bone density varies inversely as its blood supply, but whether anything is to be gained by applying the term disruptive chemiotaxis to the rarefaction which takes place in a bone graft is doubtful. The book contains an interesting account of the histology and development of bone, of the functions ascribed by various workers to the periosteum, and of the various views regarding ectopic bone formation.

RADIUM THERAPY

Traite Pratique de Curiethérapie. Généralités sur le Radium et sur la Curiethérapie du Cancer. By P. Degrais and A. Bellot. (Pp. 160; 36 figures. 36 fr.) Paris: J. B. Baillière et Fils. 1937.

One of the most recent additions to the literature dealing with the clinical uses of radium is the Practical Treatise on Curietherapy by Dr. Degrais and M. Bellot. The former of these writers is well known to English readers as having collaborated with the late Dr. Wickham in the first systematic treatise on radium therapy, which was published in 1908 and translated into English by Dr. S. E. Dore. The present work is to be completed in four volumes of about 150 to 180 pages each. The first deals with the physics of radioactivity, the construction and use of apparatus, the biological action of the rays, and the general principles upon which the radium treatment of malignant disease is based. It may be noted in passing that the term "curietherapy" was introduced by Degrais in 1919 to denote treatment by radium as distinct from *x* rays. Since these methods are so often combined the comprehensive term "radiotherapy" is used, especially in this country, to include both these methods of treat

The three remaining volumes of the present work will deal with the use of radium in the treatment of cancer in various situations, the gynaecological uses of radium in non-malignant conditions, and lastly with its dermatological applications. The general principles, which form the subject-matter of the first volume, are clearly and concisely set forth, while the illustrations in the sections dealing with apparatus are clear and informative. These indeed are the only illustrations in the book, and we think the authors have done wisely in omitting them from the sections on the biological actions of radiation. The histological changes set up by the action of radium or *x* rays need to be studied at first hand in the laboratory. In discussing the biological effects of radiation the authors maintain that β rays, so far from only having an indiscriminate caustic effect, have, under proper conditions of dosage, a selective action in the same way as the γ rays. For this reason they advocate the retention of β radiation in the treatment of cutaneous lesions, a matter which is to be dealt with in the concluding volume.

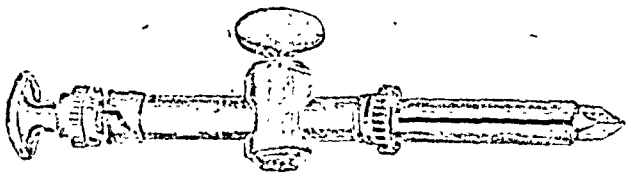
Judging from the first volume, we can cordially recommend this treatise as a clear and concise textbook for those training to become radiotherapists.

Notes on Books

Professor ROSCOE R. HYDE, who directs the laboratories of immunology and filterable viruses in the School of Hygiene at Johns Hopkins University, has written a small book entitled a *Laboratory Outline in Filterable Viruses* the aim of which is to guide the practical work of the student. It is divided into two parts. The first comprises those exercises designed to instruct the student in the nature and behaviour of viruses, while the second part is concerned with the histopathology of virus diseases. Presumably this book is intended primarily for those attending the course of virus study in Professor Hyde's department, and for this purpose it is probably adequate. But it is unlikely to prove of use to students elsewhere because it lacks much of the detail necessary to their instruction and guidance. So much is this so that in many places the book is little more than a syllabus of the practical exercises that the student is to carry out. In fairness to the author, however, it should be pointed out that this omission of detail is deliberate, its object being to encourage the student, under direction, to supply this for himself. The book is published in this country by Macmillan and Co. at 7s. 6d.

For the seventh edition of his *Gynaecology for Nurses and Gynaecological Nursing*, first published in 1910, Sir COMYNS BERKELEY has largely rewritten the text and in various directions brought the subject-matter up to date. He has also inserted between brackets at the end of the appropriate section the question or questions relating thereto set in the final examinations of the General Nursing Council. The publishers are Faber and Faber, and the price is 7s. 6d.

Recent developments in the treatment of tuberculosis have made it more rather than less difficult to assess correctly the part played by climatic factors. A swing of the pendulum has nowadays perhaps led to underestimation of their importance. In the little work entitled *Die klimatische Behandlung der Tuberkulose und ihre heutige Bewertung* (Berlin, Julius Springer, RM. 1.80) Professor A. BACMEISTER discusses in somewhat vague terms the beneficial effect of climate and altitude on the various forms of the disease. His arguments are not very convincing, and the main object of the paper appears to be to attract the attention of practitioners in Germany to the variety of climatological possibilities for the treatment of tuberculosis in that country.



Preparations and Appliances

TROCAR AND CANNULA FOR CLOSED DRAINAGE OF CHEST

Mr. JOHN T. MORRISON, F.R.C.S. (Liverpool) writes:

The instrument about to be described was made for me by the Genito-Urinary Manufacturing Company, who have kindly provided the attached technical description. It has been gradually devised to facilitate the provision of closed intercostal drainage in cases of empyema, both acute and chronic, the advantages of which over open drainage, in the early stage of treatment at least, require no comment.

The instrument consists of a cannula provided with a stopcock and stuffing box. Two lateral slots are cut in the lower section of the cannula each 2 mm. wide and 53 mm. long. A rotary sleeve with corresponding slots is fitted over the cannula acting as a shutter. The rotary movement of the sleeve is limited by a stopping pin which brings the slots in the

cannula and those in the rotating sleeve into apposition. At the upper end of the instrument a detachable stuffing box prevents the entrance of air during withdrawal of the trocar point. When the trocar point is withdrawn until it comes to rest against the stuffing box the stopcock can be closed and the stuffing box with trocar detached from the cannula.

With local anaesthesia directed particularly to the extrapleural tissues and the edges of the ribs bounding the chosen space, the trocar and cannula is inserted through a short incision with a semi-rotatory movement till it is felt to enter the pleura, the lateral slot being closed. The trocar is now withdrawn, the stopcock shut, and the stuffing box removed. A rubber drainage tube with terminal lateral eye, previously chosen to fit the lumen of the cannula exactly, is inserted and, as the stopcock is opened, pushed down till it reaches a marked point indicating that it has reached the pleura. If there is difficulty in doing so the trocar is reinserted and the instrument pushed a little further in. The end of the drain is now opened under water to ensure that pus is flowing, and then re-closed with a suitable spigot. The sleeve on the cannula is rotated so as to open the slot and a fine bayonet-pointed needle picking up skin *en route* transfixes the drain through the opened slot. This needle may now be held firmly against the chest wall, ensuring that the drain remains exactly where placed in the chest, during withdrawal of the cannula. The needle is then removed and the drain fixed in position *secundum artem*. The object of the sleeve, which keeps the slot closed until a drain is in place to convey pus directly to the exterior, is to prevent the leakage of pus and possible entrance of air which would take place if the slot was permanently open. The illustration is approximately half scale.

CITRATED FERROUS CHLORIDE

Tabloid ferrous chloride citrated (Messrs. Burroughs Wellcome and Co.) is a ferrous preparation which is claimed to resist oxidation and deliquescence under all climatic conditions. The tabloids contain 3 grains of the compound and are sugar coated.

Ferrous salts are in many ways the most satisfactory means of administering iron. Unfortunately most ferrous preparations oxidize on prolonged exposure to air. A systematic search for a stable ferrous compound resulted in the inclusion in the *B.P. Addendum* (1936) of citrated ferrous chloride.

USE AND ABUSE OF BENZEDRINE

Although benzedrine was discovered by Barger and Dale in 1910, this sympathomimetic substance attracted no special attention until in 1930 pharmacological investigations and animal experiments were carried out by a number of workers, among whom were Alles (who first synthesized it), Piness, Tainter, Hartung and Munch, and others. It was found that benzedrine had a pressor effect, and evidence produced by Tainter suggests that this is not due to pure sympathetic stimulation or to stimulation of muscle. An action on the higher centres of the nervous system was also observed, and the therapeutic possibilities of this have excited much interest. Following the observations that the drug could rouse animals from barbital narcosis and produce insomnia in man, Prinzmetal and Bloomberg[1] used it in the treatment of narcolepsy and found it superior to ephedrine in the prevention of attacks—work that was confirmed by Ulrich, Trapp, and Vidgoff.[2] In this country Peoples and Guttmann,[3] working at the Maudsley Hospital, gave the drug in doses of 10 to 80 mg. to depressed patients and to a group of normal persons: they claimed to demonstrate a close connexion between blood pressure and emotion, but in a later paper Guttmann and Sargant[4] observed that a patient with only a trivial alteration of blood pressure might show a pronounced psychological reaction, and vice versa. According to Peoples and Guttmann the effect on the vegetative nervous system was slight, and parallel studies on the blood sugar level showed no variations beyond normal limits. Depressed patients overcame their retardation and talked more, and some degree of euphoria was noted. These striking changes in an illness which had so far proved resistant to treatment led to a therapeutic optimism which was not altogether tempered by these authors' scientifically cautious conclusion—namely, that although the drug was a promising therapeutic ally further investigation was needed to show whether permanent administration produced adaptation, habituation, or even addiction. Nor have these questions yet been answered, although Prinzmetal and Bloomberg have given the drug daily for over a year and others for periods up to six months without ill effect. Sargant and Blackburn[5] demonstrated improved intellectual performance, as measured by intelligence tests, in psychotic patients after the administration of benzedrine. In their series of 250 cases Guttmann and Sargant found that mild depression with mental retardation is the most favourable psychological disorder for benzedrine therapy; that anxiety symptoms are intensified by the drug; but that no general statement of its effect in schizophrenia is possible owing to the variety of the clinical manifestations of the latter. They regard the optimum dosage as 10 to 30 mg. a day, with which most observers agree. Davidoff and Reifenstein,[6] in a careful clinical study of a group of psychotics, stress the need for care in the use of the drug, and consider that it is most safely administered under close in-patient observation, and that its use in out-patient practice should be undertaken with considerable caution. Benzedrine has also been given to cases of post-encephalitic Parkinsonism, and appears to be of value when drowsiness and lack of energy predominate, although it is usually most effective when prescribed in combination with scopolamine or stramonium: it abolishes or reduces the frequency of oculogyric crises.

Applied locally, benzedrine was first used to relieve congestion of the nasal mucous membrane. As was to be expected, it has also been tried in other conditions. Myerson and Ritvo,[7] for example, consider it of value in the relief of intestinal spasm, and believe that it will be of use in radiological investigation of the gastro-intestinal tract, facilitating differential diagnosis between functional and organic spasm. Benzedrine increases the gastric secretion of hydrochloric acid and of pepsin, and may be of value in differentiating functional from organic achlorhydria. It is possible that its use will be extended to other conditions—for example, in raising the blood pressure in peripheral circulatory failure. Korns and Randall[8] treated a case of orthostatic hypotension with benzedrine with satisfactory results, but it would appear that in this condition ephedrine is a more potent remedy. As with any new therapeutic remedy, the discovery of contraindications follows hard upon therapeutic trials. A number of untoward psychological and physical reactions have been observed, the former including aggressiveness and other anti-social behaviour, the intensification of homicidal and suicidal trends, and hallucinatory deliria. Among the physical consequences observed are loss of weight, skin rashes, rise and sometimes paradoxical fall of blood pressure, and such cardiovascular

[8] *Amer. Heart J.*, 1937, 13, 114.

events as the case of transient heart-block recorded by Anderson and Scott[9]; it may be, however, that this was an exceptional case. Benzedrine is contra-indicated in hypertension, disease of the coronary arteries, and in manic excitement. Myerson, Loman, and Dameshek[10] found an increase in the red and white cell counts, the former often by as much as one to three millions and the latter being doubled or even quadrupled. This was accompanied by a striking polymorphonuclear leucocytosis. Schube, Raskin, and Campbell[11] regard these phenomena as transitory, and did not observe any permanent alteration in the blood picture either during or long after the administration of benzedrine. In our present issue at page 615 Dr. Ivor Davies records a case of acute aplastic anaemia following self-administration. The drug appears to have no effect on the basal metabolic rate.

The chief therapeutic use of benzedrine so far has been in the treatment of narcolepsy, of post-encephalitic Parkinsonism, and of mild depression, but its application in psychiatry will probably be limited. Not only is it at best a palliative but the extreme variability of its effect in different patients and in the same patient at different times restricts its usefulness. In view of the wide range of physiological and psychological reactions which attend its administration further detailed study under controlled conditions is necessary and desirable. The unrestricted sale of this drug and its indiscriminate employment whilst the whole matter is still in the experimental stage is to be deplored. It is also regrettable that the wide publicity it has received in the Press may lead to it being taken indiscriminately by those in search of a new fillip to the flagging body or mind.

A HOSPITAL STOCK-TAKING

One person out of every thirty-seven in the British Isles is a patient in the wards of a voluntary hospital during the year, and one out of every eight an out-patient. Over a million surgical operations under a general anaesthetic are carried out in these hospitals during the twelve months. The amount expended by voluntary hospitals, more than fifteen and a half million pounds, is greater than the cost to the State of police and prisons and the execution of law and justice, greater than the amount spent by the State on old age and widows' and orphans' pensions, and more than one-third of the cost of the Army, at least as the cost stood before the recent rearmament. Such are some of the figures to be gleaned from the seventh issue of *The Hospitals Year-Book*,[12] which again comes forward with a vast amount of information so tabulated that almost any fact regarding hospitals that can be expressed in figures may be elicited at a glance or with a little search.

One of the sets of tables furnishes an analysis of the sources from which the voluntary hospitals continue to derive their income. Taking the figures for more than 1,000 hospitals, and the year 1935 (the latest year for which completed statistics are available), and calculating to the nearest £, it appears that "voluntary gifts" work out at £68 per available bed, payment for services rendered (including patients' contributions) at another £53, interest on investments at £23, and other receipts and extraordinary income bring up the total to £167. We put voluntary gifts in quotation marks because in this category are lumped workmen's contributions and payments under contributory schemes, which can hardly be described in the same way as subscriptions and donations from detached benefactors, being in fact of the nature of payment for anticipated services. A directory of contributory schemes embodied in the *Year-Book* includes nearly 400 entries, many of them, of course, quite small local affairs, but they are headed by the Hospital Saving Association with an income in 1935 of £844,000, the Birmingham Hospitals Contributory Association, with £352,500, the Sheffield and District Association of Hospital Contributors, with £163,000, and the Merseyside Hospitals Council, with £153,000. In addition there are about forty provident schemes for treatment in private wards, half of them organized under the control of individual hospitals and half of them independently. Nevertheless, despite the growing tendency to arrange hospital finance on more or less commercial lines, voluntary subscriptions and donations show little abatement. There is some falling off in London, but the provinces support their hospitals nobly, and in Scotland the stream of generosity has been greatly accelerated. In Scotland the subscriptions and donations (apart from organized workmen's schemes) have gone up by £55,000 in two years. Legacies, too, are on the upgrade. The total amount bequeathed to the hospitals of the United Kingdom in 1935—namely, £2,382,736, of which only about half a million was earmarked—was considerably above the figures of the two preceding years, and here again Scotland was conspicuous, the legacies amounting to £85,000 more than the previous year, and to £154,000 more than the figure for two years ago.

The *Year-Book* is not only a statistical compendium, but a directory, and although issued under

voluntary hospital auspices it contains a full list of municipal and public assistance hospitals, municipal maternity hospitals and homes, and county and borough mental hospitals. The outstanding event of the hospitals year has been the report of the Voluntary Hospitals Commission. The editor of the *Year-Book* (Mr. R. H. P. Orde) points out that the reforms therein advocated must be self-imposed. He writes:

"The organization which the Sankey Report urges is a self-created one: a central body representative of regional divisions. Its task, both centrally and regionally, is to collect and to distribute information, and by those persuasive powers that come from knowledge of the work to be done and from a sympathetic understanding of the views of those undertaking it, to bring about gradually and in the light of experience system and order where little or none exists at present. The organization must also possess the power of the purse. The task of bringing such an organization into being the Sankey Report places upon the shoulders of the British Hospitals Association. Time, perseverance, and common sense are demanded, and an absence of that attitude of mind which sees difficulties where none exist."

AUSTRALASIAN COLLEGE OF PHYSICIANS

The Australasian College of Physicians, which now comes into existence, has been planned to some extent on the pattern of the Royal College of Physicians of London, with variations to suit the needs of a community whose professional schools and leaders are scattered sparsely through a huge continent where means of communication are not yet fully developed. In the new Australasian College the proportion of Fellows from each State to sit on the council will be arranged in advance so as to make its governing body geographically balanced. The president will be elected by the council and not, as in London, by a comitia of all the Fellows; and the members of the college will have representation on the council. The assumption of responsibility for a qualifying examination is not contemplated: the college will have no licentiates. Its two grades will be that of membership, conferred by a board of censors after examination, or, as here, on published work; and that of fellowship, awarded to those chosen by the council year by year from among the members of more than four years' standing. Foundation Fellows will include all those recognized as teachers of medicine by the medical faculties of the universities of Australia and of New Zealand. The college will absorb the Association of Physicians of Australasia, whose members will become Foundation Fellows. It will carry on the work of that association, including the organization of an annual meeting at different centres at which scientific communications are submitted. In drawing up its constitution the new college has taken full advantage of information put at its disposal by the Royal College of Physicians of London, which last winter appointed Sir Edmund Spriggs as an emissary. His visit to Australia was followed by one to this country from Sir Charles Blackburn (Sydney), Dr. S. V. Sewell (Melbourne), Dr. L. S. Latham (Melbourne), Dr. A. W. Holmes à Court (Sydney), and Dr. E. B. Gunson (Auckland), who conferred with Lord Dawson of Penn and other colleagues at Pall Mall East. Apart from the promotion of research in clinical medicine and the dissemination of knowledge, the Australasian College will, it is hoped, serve as a meeting point for physicians and provide opportunities for discussion and common action when legislative or other measures affecting the national health arise. The first president is Sir Charles Blackburn, consulting physician to the Royal Prince Alfred Hospital, Sydney, and the vice-president Dr. S. V. Sewell, physician to the Melbourne Hospital.

TREATMENT OF MÉNIÈRE'S SYNDROME

The difficulty in treating cases of vertigo has until recent years arisen from two factors. The first of these was the lack of proper aetiological classification, and the second was the lack of effective methods of treatment. There is now a tendency to divide such cases into two main groups under the names of aural vertigo and Ménière's disease. This nomenclature can scarcely be defended on scientific grounds, but if it serves a practical end it may be justified. It is intended to differentiate between milder attacks of vertigo arising from disease or physiological disturbance in the ear and severe attacks of vertigo, vomiting, deafness, and tinnitus originating in the auditory nerve. Thus, toxic conditions such as poisoning from tea, tobacco, or even focal sepsis may be considered to produce aural vertigo, and disease in the labyrinth must be included. Where a cause can be found for the symptoms of aural vertigo by taking a careful history of the case the treatment is evident. Apart from this it has been customary to rely upon bromides and luminal, which in fact rarely do good and may aggravate the symptoms by producing drowsiness and dizziness. The suggestion of Mygind and Dederding that the attacks are due to disordered water metabolism has caused this line of investigation to be followed, and it appears that it is not so much the water as the electrolytes of sodium which are responsible. The treatment based on this is to eliminate salt from the diet and administer with each meal 45 grains of ammonium chloride, which prevents the storage of sodium. Water need not be restricted. Madelaine Brown[1] reports twelve cases of severe attacks of vertigo and vomiting in patients suffering from deafness and tinnitus which have ceased under this treatment. Ménière's disease is encountered in the absence of any evident lesion. The attacks of vomiting, vertigo, and even unconsciousness are considered by Dandy[2] to have origin in the auditory nerve, and he has shown in a recent paper that in a small percentage of cases a vascular or other lesion can be demonstrated at operation. His cases include an acoustic tumour, angioma of the cerebello-pontine angle, aneurysm of the basilar artery, and five cases in which large arterial loops produced strangulation or compression of the auditory nerve. In more than half the

[1] *J. Amer. med. Ass.*, 1937, 108, 1158.
[2] Ibid., 1937, 108, 931.

cases, however, in which the posterior fossa is exposed no pathological change is discovered, but the symptoms are entirely relieved by division of the eighth nerve. Donald Munro[3] also has reported on fourteen cases, ten treated by section of the eighth nerve, in one of which both auditory nerves were divided in order to obtain relief, and he draws attention to the physiology of the labyrinth as expounded by Rademaker. Normal labyrinthine reactions occur in response to rectilinear vertical or to rotary movements, and initiate the effort to return the head and eyes to a normal position. The tendency to overcorrection is prevented by the proper integration of the two labyrinths, which maintains a static position in space by control of postural tonus. One labyrinth alone can be adapted to accomplish this, but if both labyrinths are dead this function is lost until it is substituted by visual and proprioceptive reactions. Welti[4] has recorded the first case of total section of the eighth nerve performed in France with complete and permanent success, and Aubry and Ombredanne[5] have later also given accounts of the excellent results from partial section of the eighth nerve, cutting the vestibular portion and preserving hearing by sparing the cochlear division, as Dandy recommends. Increasing experience indicates that the operation of choice is division of the eighth nerve rather than direct surgical attacks upon the labyrinth, as these fail in about 30 per cent. of cases. It is clear, however, that treatment upon medical lines as recommended by Mygind[6] should be given a fair trial before resorting to so drastic an operation.

THE ANAEMIA OF HEPATIC CIRRHOSIS

A mild degree of anaemia and of macrocytosis are present in the majority of patients with liver disease, and in a minority both the anaemia and the macrocytosis may be severe.[7] It is not possible to explain the macrocytic anaemia of disease of the liver by jaundice, bad diet, achlorhydria, or gastro-intestinal defect, as cases occur in which all these factors can be excluded. Macrocytosis is not necessarily an indication of bone-marrow derangement, as external influences acting on the circulating red cells may alter its volume without affecting its content of haemoglobin. This swelling of the cell will result in its being less saturated with haemoglobin. The quantity of albumin in the plasma is diminished at some time in every case of chronic advanced disease of the liver,[8] and this in itself may lead to swelling of the red cells, as their volume tends to be inversely proportional to the level of serum albumin. Six cases of advanced portal cirrhosis, all with macrocytosis and low serum albumin, were described by Bethell and Rottschaefer,[9] who found that the amount and concentration of haemoglobin in the corpuscles were normal, indicating that a developmental factor was at work, and there was actually a disturbance of blood formation. In a heterogeneous group of other diseases of the liver, including hepatitis, abscess, and carcinoma, both the serum albumin and the corpuscular concentration of haemoglobin were low, indicating a simple circulatory cause. It thus appears probable that macrocytic anaemia due to disturbance in the development of the red cells in the marrow is restricted to, or at any rate is much more prone to occur in, portal cirrhosis. Shumacker and Wintrobe[1] were able to reproduce the macrocytic anaemia of disease of the liver in dogs and rabbits by repeated poisoning with carbon tetrachloride. The anaemia was proportional to the severity and duration of the chronic liver damage, and the blood picture resembled very strikingly that of patients suffering from pernicious anaemia. In man the bone marrow in these cases may be indistinguishable from that of pernicious anaemia. Some writers have attributed the macrocytic anaemia of cirrhosis of the liver to defective storage of the liver principle, and it is true that assay of these livers, which has now been carried out in several human cases, has shown that little or no anti-anaemic principle could be extracted. Nevertheless, this cannot be the whole explanation, for the results of treatment of the macrocytic anaemia of portal cirrhosis with preparations of liver by mouth and parenterally are disappointing. Moreover, enough anti-anaemic principle should be stored in the kidney, the brain, and other reservoirs. But although kidney and brain are effective remedies by mouth, Dakin, Ungley, and West[2] were unable to extract active haemopoietic principle from them by methods which had been successful with liver. The mechanism of pernicious anaemia is more complicated than was at first realized. It seems unlikely that the part played by the liver is passive or that it acts merely as a storehouse for material elaborated in the alimentary tract.

MENTAL HEALTH OF PRISONERS

Psychological science can make such an important contribution to the study and treatment of crime that no opportunity should be lost of explaining its possibilities to the public. Dr. W. Norwood East, in his report as Medical Commissioner of Prisons,[3] regrets the fact that magistrates still convict and sentence offenders whom they know to be insane or mentally defective. On April 20, 1934, the Home Office issued a circular to all courts of summary jurisdiction pointing out the grave objections to a system which neglects to take into consideration the relevant medical factors when deciding a case. Dr. Norwood East finds it difficult to appreciate the attitude of justices who persist in sentencing prisoners before asking for a report on their mental state. He regards this practice as undesirable and possibly unjust. It is dangerous to generalize, but one of the principal

reasons for this attitude is probably the rooted distrust of psychology that is inherent in the national character, and especially in those of the generation which chiefly occupies the petty sessional bench. It would not, of course, be fair to say that magistrates as a class are hostile to psychological knowledge, for the Magistrates' Association has always shown keen interest in and sympathy with the psychological approach to the problems of the delinquent. Time and quiet persistent instruction are the best means of bringing magistrates as a whole to enlist the help of the psychological physician in dealing with those offenders whose conduct has been substantially the result of disordered mentality. These do not, of course, comprise the whole or even perhaps the majority of all prisoners. Nevertheless, it seems from Dr. Norwood East's report that justices could do more than they do at present in giving information as well as asking for it. The Home Office circular of 1934 stated that medical officers of prisons derived much assistance in their examination into the mental condition of a remand prisoner if the court sent them all available information on his life history and mental history. In a few areas excellent and valuable information is forwarded to the prisons, but in general, as the medical officer of Brixton Prison reported, there is no real liaison between the court and the medical officer. The psychologist's assessment of a prisoner's mental condition would be more valuable to the justices if he held the key to the man's "life style." There is a wholesome and growing tendency for courts to look more at the offender and less at the offence. Whatever may be the possibilities of treating delinquency by psychological means, medical psychologists can greatly help the administration of justice if they are given fair opportunity for investigation and report and if the courts act on their advice.

THE DANGEROUS AREA OF THE FACE

Fatalities are unfortunately not very uncommon from the failure to institute prompt and energetic treatment, but failure to withhold the scalpel in a case of facial furunculosis or carbuncle—especially when the infected area is on or near the upper lip—may be disastrous. This has been well brought out by a recent study of infections in the dangerous areas of the face by Urban Maes[1] of New Orleans. Referring to infection in the vicinity of the upper lip, he says, "This is a condition in which procrastination reaps shining rewards, in which zeal and promptness are attended by fearful consequences. The physician who treats such cases will lose fewer of them if he takes his stand on the firm rock of surgical nihilism." Maes has collected twenty fatal cases of lesions in the dangerous area and twenty-four fatal cases of infection of other parts of the face not usually included in this area. Fifteen of the twenty fatal cases were in patients between 15 and 28 years of age. The upper lip area, in common with the subaponeurotic space beneath the scalp, is known as a "danger area" because of the direct intracranial venous connexions which permit the passage of infective thrombi into the intracranial venous sinuses. The venous trunk formed by the angular and (anterior) facial veins has connexions with the cavernous sinus, both by way of the ophthalmic vein and through the pterygoid plexus. Interruption of the connexion through the ophthalmic vein has been suggested and practised by ligature, but this involves an incision and tissue damage and the danger of disturbing and loosening clot by manipulations. Maes states that he has never seen any early case in which he thought the procedure was indicated or a late case in which he thought it could do any good. He concludes that ligation is theoretically correct but of little practical value. As long ago as 1852 H. Ludlow drew attention to the fatal character of boils and carbuncles on or near the upper lip. He described six cases, three of which were fatal, and wrote against local measures which "demolish the feeble bulwarks which oppose the spread of the disease"; but it remained for Logan Turner of Edinburgh in 1926 to work out the exact pathways by which the infection is spread. The rapidity of the spread and of a fatal termination in some of these cases following surgical intervention is tragic when one considers the apparently trivial character of the initial lesion. The practical lesson is that a pimple or other infected lesion on or near the upper lip is a danger signal: as Maes says, "Lay persons must learn to keep their hands off their faces, and physicians must learn to keep their hands off their patients' faces." If the lesion is of any but the simplest character rest in bed, with nursing care, is advisable; this includes the prohibition of speech and laughter, so that movement and trauma are reduced to a minimum. Nasal feeding should be instituted in graver cases and local treatment limited to warm compresses. Many surgeons now advocate conservatism in the treatment of boils wherever they occur.[2] In the treatment of boils on the face such conservatism is vital.

DR. ANTOINE BÉCLÈRE: CORRECTION

We much regret that through a confusion of names an obituary notice was published on September 11 (p. 562) of Dr. Antoine Béclère, the eminent French radiologist, President d'Honneur de la Société de Radiologie de France, Membre de l'Académie de Médecine, Honorary Member of the Royal Society of Medicine. Mdlle Antoinette Béclère informs us that her father is happily in good health. It was Dr. HENRI BÉCLÈRE who died last month; he also practised as a radiologist, and was Dr. Antoine Béclère's cousin. Dr. Antoine Béclère's address is 122, Rue la Boëtie, Paris, 8me.

The Harveian Oration before the Royal College of Physicians of London will be given on St. Luke's Day, Monday, October 18, at 4 p.m., by Sir Arthur F. Hurst, whose subject is "Observation and Experiment and the Physiology of the Stomach."

ANAESTHESIA IN GENERAL PRACTICE

This is one of a series of articles, contributed by invitation

ENDOTRACHEAL ANAESTHESIA

BY

IVOR LEWIS, D.A., M.R.C.S., L.R.C.P.

Although the practice of endotracheal anaesthesia has in the past been limited to professional anaesthetists, there is nowadays an increasing number of men, both in provincial towns and in country districts, who are devoting themselves especially to anaesthesia and who are adopting modern methods to a very advanced degree. Familiarized as students with modern apparatus, they no longer regard an anaesthetic machine as a complexity beyond their comprehension. Proficiency in endotracheal technique is one of the more obvious manifestations of the first-class anaesthetist, but it should be the duty of every man who practises anaesthesia at all regularly to make himself proficient in this branch and to be possessed of the necessary equipment. Apart from adding to his capacity as an anaesthetist it places in his hands a method of artificial respiration that is second to none. Before undertaking this technique proficiency in ordinary anaesthetic methods and the possession of an efficient machine are essential. A post on the staff of a hospital is advisable, as opportunities for practice are more frequent and take place under conditions of greater safety.

Inhalational Method

The method of insufflation, in which the anaesthetic vapour is blown through a small bore catheter and returns around the tube or through a second catheter inserted for the purpose is now almost effete. Inhalation is the accepted modern usage. A wide-bore rubber tube as designed by Magill is inserted either nasally or orally into the trachea, which it fits fairly closely. A metal angle-piece and a short length of rubber tubing connect with an exhaling valve of the McKesson type. The source of anaesthetic vapour may be either intermittent (McKesson) or continuous (Magill, Boyle, or motor pump). The latter must of course have a reservoir bag. It is useful to remember that in an emergency, such as the failure of the machine, direct connexion by a length of rubber tubing from the angle-piece to a gauze-covered funnel or Hahn's cone on which ether is dripped provides a simple and effective method of dealing with an apparently hopeless situation. The indications for endotracheal anaesthesia are as follows:

1. Operations on the head and neck, including, for example, ear, nose, and throat, dental, palatal, and plastic operations, but excluding operations on the thyroid and the eyes. Foreign matter is excluded from the upper air passages and lungs, and the anaesthetist is removed from the field of operation.

2. Chest surgery. An academic reference only as this is definitely an expert's work.

3. Operations involving an inconvenient posture—for example, operations on the brain, spine, or kidney, and any procedure which necessitates a complete Trendelenburg position.

4. Surgery of the upper abdomen and oesophagus because of the diminished respiratory excursion that can be attained.

5. Cases of intestinal obstruction with vomiting. If endotracheal anaesthesia is combined with the insertion of a stomach tube regurgitated material is prevented from entering the trachea.

6. All desperate risks where artificial respiration is likely to be needed.

Absolute contraindications are thyroid operations because of the definite risk of tracheitis produced by surgical handling of the trachea, and eye operations in which it is of vital importance that the patient should not cough even once. Infections of the upper air passages and abnormalities of the larynx are relative contraindications.

Technique

There are three important points.

The first is preparedness. Every detail of the anaesthetic armamentarium should be present and in working order. The moment of inserting the laryngoscope into the mouth is not the time to discover that the battery is dead. Secondly, for oral intubation deep anaesthesia is essential, especially for beginners. Thirdly, for nasal intubation the use of carbon dioxide is essential for the best results. The aperture of the glottis is widened and the strong inspirations tend actually to suck the tube into the trachea.

The use of a 20 per cent. cocaine spray is advocated by many competent authorities, but bearing in mind the toxicity of this drug and the possibilities of idiosyncrasy I am not convinced that its routine use is justifiable. It is said to facilitate introduction by making the larynx insensitive, but the beginner would be better advised to concentrate on other details in his technique.

Oral Intubation

The beginner should first make himself proficient in this method, so that when blind nasal intubation fails the tube can be inserted into the trachea under direct vision, using the laryngoscope and Magill forceps. The patient is deeply anaesthetized by some suitable method to which the anaesthetist is accustomed. The head should be in the normal position, supported by one pillow. Hyperextension should be avoided. In the procedure about to be described it will be noticed that the right hand is used to introduce the laryngoscope. Although this involves a change of hands later I am convinced that it is sound, as the majority of people are right-handed and the introduction can be done with far greater facility and accuracy with the right hand. Furthermore, the left hand in opening the mouth does not obstruct the view, as tends to be the case when the hands are reversed. The procedure for oral intubation is as follows.

With the index finger of the left hand pull on the upper teeth; this produces slight extension and opens the mouth. With the second finger of the left hand depress the point of the chin. This opens the mouth well and keeps the lower lip from being nipped between the laryngoscope and the teeth. If the mouth cannot be opened by this manœuvre the patient is too light and the anaesthesia must be deepened. With the right hand introduce the laryngoscope to the right of the midline, keeping the tongue to the left. Following the natural curve of the mouth the base of the tongue is reached, where the epiglottis will be seen as a pink object hanging into the field of vision. This is hooked up by the tip of the laryngoscope, to which a lifting movement is now imparted. At this point it is important to avoid pivoting on the incisors, as this is the moment when the teeth tend to be damaged. The larynx

should now be visible, the white vocal cords being easily recognized.

Taking good care to maintain this position, the grasp of the laryngoscope is changed from the right hand to the left. The lubricated tube is now inserted with the right hand. It must be pushed boldly and firmly, as it tends to be deflected by the slightest obstruction if it lacks momentum. It is important to see that the tube has its concavity upwards on introduction so that it will curve naturally up to the glottis when it leaves the end of the spatula. If held in the reverse position it will inevitably fall away and enter the oesophagus.

Beginners often find it difficult to decide whether the tube is in the trachea or not, as when the tube is in position it obstructs the view through the laryngoscope. This is particularly so when the introduction of the tube is immediately followed by convulsive heaving. In such a case the tube should not be connected to the machine until there is no doubt that the respirations are taking place through the tube. It must be borne in mind that a tube in the oesophagus will cause laryngeal spasm, and the accompanying heave may blow gas from the stomach out through the tube, so that it appears at first to be in the trachea.

Before withdrawing the laryngoscope place a Mason's gag in the left side of the mouth. This prevents damage to the teeth by the laryngoscope and also biting on the tube when the laryngoscope has been removed. Withdraw the laryngoscope, taking great care not to remove the tube at the same time. Connect the angle-piece to the anaesthetic apparatus.

When quiet anaesthesia is resumed the mouth should be packed with gauze or bandage soaked in liquid paraffin. This should be done with care and gentleness—rough packing, or packing while the patient is heaving, is the commonest cause of sore throat after intubation. The tube is finally secured with strapping and castor oil drops put in the eyes.

Nasal Intubation

Except for operations upon the nose or palate the nasal route for intubation is the method of choice of the experienced anaesthetist. The anaesthesia need not be so deep, since the muscles of the lower jaw do not have to be relaxed—in fact, it can be done under gas and oxygen alone—and there is no danger of damaging fragile teeth. Dexterity in blind intubation is only acquired after long practice, and it is as well for the beginner to have the laryngoscope and Magill forceps at hand, and to have the patient well anaesthetized. A properly curved tube of the right consistency tends naturally to take an anterior course on passing through the nose and reaching the pharynx. This will bring the point up to the trachea rather than to the oesophagus. A tube that has lost its curve will remain on the posterior pharyngeal wall throughout its course and will go straight on into the oesophagus. At the other extreme an excessively curved tube will take such an exaggerated forward course that it passes the glottis almost at right angles to impinge upon its anterior rim.

Thus it will be seen that the selection of the tube is of prime importance. Special tubes have been devised by Magill which fulfil very well all the requirements of curvature and consistency and combine a thin wall, which gives maximum calibre, with sufficient rigidity to prevent kinking. Even these tubes may with age and lack of proper care lose their characteristics. They are best stored in a large round tin, so that their normal curve is maintained. Too small a tin will exaggerate the curve and make them very difficult to use; a straight narrow box will cause them to lose their curve altogether. Prolonged boiling should be avoided, as it makes the tubes flabby—they are best sterilized in a cold solution of biniodide of mercury. The technique of nasal intubation is then as follows:

The position of the head is important. The normal position when the head is supported by a single pillow is best, but some variation may be necessary in certain cases, as will be indicated later. The nose is inspected for the presence of any obstruction, and the side with the freer airway selected. A congested mucous membrane may be sprayed with 20 per cent. cocaine, which some authorities use as a routine. The patient is anaesthetized to a depth which will vary with the anaesthetist's experience of intubation. The beginner should anaesthetize as for oral intubation. Carbon dioxide—about 10 per cent.—is then administered until the respirations are deep and rapid. The lubricated tube is introduced into the nose and as little time as possible wasted in pushing the point as far as the pharynx. It should be remembered that once inside the nares the direction is backwards at right-angles to the line of the body.

Breathing can now be heard through the tube, and from this point onwards the movement of the tube must be bold and rapid. A slowly moving tube is easily deflected from its course by any obstruction if it is not in exactly the right line. In an ideal case it immediately enters the trachea. The respirations can be heard coming strongly through the tube; if the patient is only lightly anaesthetized he will give a convulsive heave, but as he is unable to close his glottis no cough will be heard. It is possible to be deceived in cases in which there is vigorous breathing through the opposite nostril, as the tube may be plunged into the oesophagus while the respirations heard in the neighbourhood of the nose are assumed to come from the tube. This error may be avoided by closing the other nostril with a finger.

If the tube does not immediately enter the trachea the beginner should promptly introduce the laryngoscope into the mouth and expose the glottis. The tube will be seen emerging from behind the palate. Any obvious deflection can be corrected by rotating the tube, and it is often possible to guide it into the trachea by this manœuvre alone. Failing this the Magill forceps must be used while an assistant pushes the tube onwards through the nose.

When it is decided not to fall back on the laryngoscope it is necessary to have a properly rationalized plan of action. The tube is not in the correct line. This may be due to lateral deflection to either side, or displacement antero-posteriorly, or, as is most common, a combination of both. Lateral deflection may be detected by a finger on either side of the cricoid, and is corrected by rotating the tube until the breathing is heard at its loudest. The antero-posterior position of the point is varied by having an assistant to lift the head vertically while the jaw is held up by the anaesthetist to prevent flexion of the head. Flexion is the last movement made, as it is effective only in the case of excessively curved tubes, and as most tubes fail in curving forward the vertical lift is far more certain to be successful.

Dangers and Complications

There are two sources of possible trauma. The laryngoscope during intubation may injure the lips, teeth, tongue, pharynx, or, finally, the glottis, which last may lead to acute oedema, especially in young children and infants. Trauma caused by the packing, on the other hand, may be due to absence of lubrication, too rough packing, or the insertion of the pack while the patient is still heaving. Post-operative sore throat, and even sloughing of the palate and pharynx, may be produced. Tracheitis is uncommon except where there has been much movement or manipulation of the neck, as in thyroidectomy.

Misplacement of the tube may be dangerous. If inserted into the oesophagus it may cause inflation of the stomach and intestines with anaesthetic vapour. With the low pressures now in common use it is unlikely that any serious damage will follow, but the surgeon will be incommoded in an abdominal operation by the distended gut. If this should occur a tube should be left in the stomach to assist the expulsion of the gas.

When too long a tube has been used it may enter the bronchus, more usually the right. It happens more often during oral intubation as the distance between the external orifice and the bronchus is shorter than by the nasal route. It should be remembered that the tubes as supplied by the makers are of generous length, and while they may be ideal for nasal intubation they will certainly need to be cut down for oral work. Therefore it is safer to keep two sets of tubes in order to avoid this accident, for tubes cut down to a safe length for the mouth become almost useless for blind nasal intubation. It is impossible to dogmatize about the average distance between the teeth and the bifurcation of the trachea, for each case must be judged individually. It is quite a simple matter to fit the patient roughly with a tube by external comparison with the neck, and if care is taken not to insert the point of the tube more than two inches beyond the vocal cords the bronchus need never be entered.

Early detection of the fact that the tube has entered a bronchus is often difficult, as the signs resemble those of too light anaesthesia. There is heaving due to irritation of the bronchus, and since only one lung is affected by the vapour the effect both of the anaesthetic and of the oxygen percentage is almost halved. Therefore, if with a normal anaesthetic concentration and oxygen percentage the patient still remains too light and is slightly cyanosed, the anaesthetist should always suspect that the bronchus has been entered. The respirations when the heaving has subsided tend to be short and jerky, and if at this point the tube is disconnected near the machine and applied to the ear the noise heard will be of a higher pitch than normal and will resemble that heard through a partially obstructed tube. Moist sounds emanating from the opposite lung will also be detected. Should the condition be allowed to persist it may result in the complete collapse of the other lung with characteristic deformity of the chest. The treatment is, of course, withdrawal of the tube. This should be done carefully, as the patient is likely to have an unusually short trachea and it is very easy to pull the end of the tube completely out of the trachea—a disastrous procedure in the middle of a facial operation.

A further possible complication is inhalation of the tube caused by a too loosely fitting angle-piece. The tube slips off the angle-piece and is inhaled out of reach. In the case of an oral tube, a gag must be put promptly between the teeth before the patient becomes light enough to clench them or the situation will become serious owing to the obstruction to the respiration. The laryngoscope is then inserted and the tube recovered by means of a Magill's forceps. In the case of a nasal tube there is not so much prospect of respiratory obstruction. The anaesthesia may be deliberately deepened until the jaw muscles are relaxed. It is usually impossible to retrieve the tube through the nose once it has got well down, so the laryngoscope must be used. The tube is seized by two pairs of Spencer-Wells's forceps and cut between them. The lower half is pulled straight out, while the upper half is pulled backwards into the pharynx until it is free of the palate and then removed through the mouth.

Conclusion

At the conclusion of the anaesthetic accurate technique is of paramount importance. It is usual to remove the tube in the theatre, but it may be left in position, nasally, for as long as twenty-four hours if so desired. In such a case it should be anchored by a safety-pin. Before taking out the tube all packing must be taken from the pharynx, and any blood clot or mucus dealt with by suction or swabbing. An ordinary airway is then placed in the mouth and the patient is given 10 per cent. carbon dioxide in oxygen through the tube. When the respirations are deep and rapid the tube is carefully removed. This procedure eliminates the possibility of laryngeal spasm, which would otherwise tend to occur on movement of the tube.

FOOD AND GASTRO-INTESTINAL DISEASE IN SWEDEN

A report on *An Investigation into Questions of Social Hygiene in the Counties of Västerbotten and Norrbotten, Sweden*[1] has recently been published in English by the Royal Medical Board of Sweden under the editorship of Dr. Nils Hellström, formerly Director General of the Board. It is a bulky, well-illustrated volume of some 800 pages dealing with geographical and climatic conditions, housing, mode of life of rural population, medical examination of school children, composition of diets, basal metabolism in relation to the composition of the food, incidence of gastro-intestinal ailments and of anaemia in relation to the composition of the food, condition of the teeth, dental diseases, histopathology of the teeth with special reference to hypovitaminosis (C and D), determination of the antiscorbutic potency of vegetable products, the widespread occurrence of C-hypovitaminosis in Vasterbotten, existing Swedish institutions engaged in the promotion of public health and personal hygiene, and means for improvements in hygiene. The purpose of the present work is not only to furnish a comprehensive report on the results of this investigation, drawing attention to any points which may be of interest to the medical profession, but also to give to the non-medical reader a survey of the results obtained, as a basis for further practical work in the field of social hygiene.

Effects of Dietary Deficiencies

The main objective of the investigation was to try to ascertain the causal connexion between the dietary deficiencies prevailing in these countries and certain morbid conditions, notably lowering of certain functions of the stomach (achylia), catarrh of the large intestine (colitis), and anaemia, which appeared to be of more frequent occurrence there than in the more southerly parts of the country. To this end some 17,400 "healthy" and sick persons were subjected to careful medical examination, the composition of the food habitually used by them being at the same time carefully ascertained. The data accumulated in these ways were then subjected to critical analysis and the conclusion arrived at that the composition of the diet is the decisive factor in causing gastro-intestinal disorder and anaemia in Norrland. No investigation of this magnitude has hitherto been undertaken in connexion with the commonest of all human ailments: gastro-intestinal disease. The report has, therefore, a unique value.

[1] Hakan Ohlsson, Lund. Swedish edition, 1934; English, partly revised edition, 1937. Price not stated.

Achylia and Diet

The Swedish investigators find that an unvaried diet—designated by them the "L-diet"—consisting of refined flour, milk, potatoes, and a little butter with little or no meat, fresh fruit, and vegetables is associated with a high incidence of achylia and its accompaniments: mild gastric disorders, mostly in the form of a sense of fullness and oppression in the epigastric region, intestinal disorders mostly in the form of severe constipation and stercoral diarrhoea. While the incidence of achylia among the users of a mixed diet (itself far from perfect) was 13.5 per cent., it was 39.1 per cent. among the users of the "L-diet," amounting to 68 per cent. among the users of the diet in its most unvaried form. It was found that achylia could be produced in human beings by changing the diet from a mixed one to one having the composition given above (the "L-diet"). Further, by substituting a mixed diet for the "L-diet" the achylia usually disappeared. A marked improvement or a restitution of the gastric function occurred in 36 per cent. of achylic cases when given a mixed diet of meat, eggs, fish, fruit, and green vegetables, in spite of the fact that the period of observation was short and that the cases varied as to the degree of functional disturbance: the greater this disturbance the more unfavourable the prognosis. The investigators would therefore appear to have established their point, on statistical, experimental, and therapeutic grounds, that "the composition of the diet is the decisive factor in the frequency of achylia in Norrland."

Anaemia was also found to be associated in a significant way with the habitual use of the "L-diet." The type of anaemia has certain features similar to those in pernicious anaemia. It is not a typical achylic anaemia, nor an anaemia due to deficiency of iron. It has a hyperchromatic element. It is explained partly by the achylia, partly by the iron deficiency of the diet, and partly by B-hypovitaminosis.

Faults of the "L-diet"

As to the faults in the "L-diet" responsible for the production of the gastro-intestinal ill-health, Dr. Martin Odin (who is responsible for that part of the report dealing with diseases and their frequency with special reference to the composition of the diet) considers that this diet "to a great extent relieves the work of the digestive apparatus, owing to the fine disintegration of the food and its deficiency of meat, fruit, and vegetables. Herein perhaps lies the cause of its achylia-promoting effect." Fresh milk often aggravates the gastric discomfort of sufferers from achylia while sour or ropy milk as a rule does not. May it not be that those children in this country who "cannot take milk" are afflicted with achylia? The advisability of giving milk to ill-fed school children without other food accompaniments may well be doubted.

Vitamin B Deficiency

The "L-diet" has other faults, chief among them being a low content of the vitamin B complex and a composition which increases the need for vitamin B. Dr. Odin remarks that "the assumption of a B-hypovitaminosis would explain most of the symptoms," though he refrains from affirming that this is their explanation. For if it be it appears strange to him that his patients should exhibit no signs of beri-beri and little or none of pellagra. His perplexity is evidence of the difficulty of freeing the mind of those adjectival encumbrances—"anti-beri-beri" and "anti-pellagra"—formerly attached to the components of the vitamin B complex. This complex is one of the dietary substances absolutely necessary for physiological well-being, including well-being of the gastro-intestinal tract, and varying degrees of malnutrition due to its insufficiency in the diet are of common occurrence among the sick. Because of the high incidence of gastro-intestinal disease in his experimental animals McCarrison[2] was led to believe that a liberal supply of vitamin B is very important in maintaining the health of the gastro-intestinal tract and that its want is a common cause of gastro-intestinal ailments. Since that time an impressive weight of evidence has accumulated to show that chronic deficiency of vitamin B may be followed by serious damage to the structure of the digestive tract and impairment of its function. Among the most recent results in this connexion are those published by A. Z. Baker, M. D. Wright, and J. C. Drummond.[3] In an experiment planned to demonstrate the types of disorders which arise from subsistence for long periods on diets deficient in vitamin B, they found that the chief effect was the remarkably high incidence of gastro-intestinal ailments. The observations recorded by the Swedish observers provide additional evidence that faulty diet deficient in vitamin B is an important cause of gastro-intestinal disease.

Members of the profession in this country will be grateful to the Royal Medical Board of Sweden for making the results of its pioneer work available to them in English. We commend the report to all those who are interested in social hygiene.

Local News

SCOTLAND

Diphtheria Immunization in Edinburgh

At a meeting of the Public Health Committee of Edinburgh Corporation on September 14 it was decided to appoint an assistant medical officer at a salary of £600 to supervise the administration of a scheme of diphtheria immunization. The medical officer of health, Dr. John Guy, stated that there had been twenty-four deaths from diphtheria in Edinburgh during the first six months of the present year, but that the number of diphtheria cases had been lower during the past three years than previously. Lately, however, there had been evidence that the severer type of diphtheria experienced on the Continent was appearing in Edinburgh, and the twenty-four deaths had occurred among 510 cases. At least two-thirds of all the pre-school children and over half of the school children in the city were susceptible to diphtheria. On an average about 400 children were immunized yearly under the child welfare department's scheme. Further, the school medical department had immunized on an average about 2,800 children and general practitioners approximately 100 children of all ages each year. The child welfare department was unable owing to the size of its clinics to carry out any more immunizations than it was doing at present. It was therefore decided that the medical officer of health should be instructed to make the immunization scheme as effective as possible, and to take up with the British Medical Association the question of obtaining the effective co-operation of general practitioners with the department in the scheme. The scheme would be entirely voluntary,

[2] *British Medical Journal*, 1920, 1, 822.
[3] *J. Soc. chem. Ind.*, June, 1937, p. 191T.

but it had been found that at least 50 per cent. of all parents were quite willing that their children should be subjected to it.

Dundee Maternity Scheme

Under the provisions of the Maternity Services (Scotland) Act, 1937, a scheme drawn up by Dr. W. L. Burgess, medical officer of health for Dundee, to provide a maternity service including midwife, doctor, and, if necessary, obstetrician and anaesthetist, has been approved. The main purpose of the scheme is to make available to women who are to be confined in their own homes the joint care of a medical practitioner and a certified midwife, with the advice or help, if it should be necessary, of an expert obstetrician. All general practitioners in Dundee are to be invited to participate, and all those in special practice as obstetricians to act as specialists. A visiting obstetrician and gynaecologist is to be appointed to Maryfield Hospital at a salary of £450 and a resident maternity services medical officer in the hospital at a salary of £400. It was agreed to send copies of the scheme for comments to the local branch of the Scottish Midwives Association, the directors of Dundee Royal Infirmary, and the Dundee Branch of the British Medical Association.

Chronic Incapacity

In Scotland in recent years it has become clear that chronic incapacity among the insured population is increasing (*Journal*, August 14, p. 350). Cases in which disability has lasted for more than twelve months have reached a new high level. The committee which recently reviewed Scottish Health Services recommended that "to meet the needs of general practice it should be a definite function of the authorities administering the statutory medical services to supplement, where necessary, the existing specialist diagnostic and other facilities." The extent and kind of these requirements is already the subject of an important investigation, and it has been decided to institute a scheme whereby, for all insured persons who have been incapable of work for a consecutive period of three months, clinical and other details will be obtained from which ultimately some quantitative idea of these needs will be forthcoming. The approved society involved will notify the Department in cases in which incapacity has lasted three months. A clinical form will then be sent to the patient's doctor for completion, and this will be returned to the regional medical staff. In a certain proportion of the cases the regional medical officer will desire to examine the patient and discuss his condition with the insurance practitioner. The form suggested, in addition to routine data such as age and occupation, seeks to obtain details of the illness under consideration in respect of history, duration, and present condition, with particular reference to what, if any, diagnostic or therapeutic ancillary methods have been adopted, and whether or not any consultant opinion has been obtained.

ENGLAND AND WALES

Recruitment of Hospital Nurses

Throughout the country considerable difficulty is being experienced in recruiting to the junior grades of female nursing staff, particularly probationer nurses and staff nurses, for duty in hospitals. The London County Council has been considering proposals for alleviating the present shortage. It is borne in mind that any steps taken to deal with the immediate problem should not prejudice whatever may be the appropriate ultimate solution. Proposals have been made for raising the initial salary of staff nurses and for substituting assistant nurses for probationers in the tuberculosis hospitals, except at Heatherwood Hospital. At present, however, some relatively minor steps are to be taken. The salary rates payable to general-trained State-registered staff nurses in the Council's hospitals are £5 a year lower than those paid by nearly all the county and county borough authorities adjoining the London county area. Approximately 350 probationer nurses complete their training twice a year. The wastage rate—that is, the proportion of probationers who do not proceed to the grade of staff nurse, was 38 per cent. during 1936, and it is anticipated that the rate this year will be considerably higher. The number of vacancies in the grade of staff nurses increased from fifty-five in June, 1935, to 306 in June, 1936, and to 454 in June of this year. It is felt that every endeavour should be made to retain in the service as many trained nurses as possible, particularly as it is anticipated that 285 additional staff nurses will be required in the fever hospitals for the biennial outbreak of measles expected during the coming autumn and winter. If the position regarding the recruitment and the retention of trained staff in the L.C.C. hospitals is not improved it will be necessary to continue to employ a large number of institute nurses; the additional cost of employing an institute nurse instead of a staff nurse is approximately £100 a year. It is proposed that for one year probationer nurses who pass their central final examinations this year shall be paid on promotion to the grade of general-trained staff nurse a salary of £75 during their first year of service—that is, an increase of £10 a year. As a corollary to this, staff nurses who passed their final examination last year and are now in receipt of £70 a year are to receive an additional £5. It is also proposed that for the next year staff nurses trained outside the service should be appointed at the rate of £70 a year—that is, an increase of £5 a year—which will bring the Council's rate up to that paid in the counties adjoining London.

Queen Charlotte's Maternity Hospital

The clinical report of Queen Charlotte's Maternity Hospital for 1936 presents formidable sheaves of statistics with little or no comment, but the statistics yield much interesting information. During the year 3,726 patients were treated by Queen Charlotte's—1,216 as out-patients and 2,510 in the wards. The latter are divided into two categories—patients "booked" in the ante-natal department, who numbered 2,266, and patients, numbering 244, sent in on emergency by outside doctors or midwives, and who, in many cases, had received little or no ante-natal supervision. Brief particulars of every case are set out in a series of tables. Out of 158 cases of albuminuria admitted for treatment, one mother died: thirteen babies also died, and nineteen were stillborn. Of thirty cases of cardiac disease three mothers died and there were three stillbirths. Of twelve cases of eclampsia, one mother died, three babies died, and four babies were stillborn. In thirty-three cases of placenta praevia the maternal mortality was *nil* and the foetal mortality over 60 per cent. The results with various methods of delivery can be thus set out:

	No. of Cases	Mothers Died	Babies Died	Still-births
Induction of labour (spontaneous delivery)	204	2	13	28
Induction of labour (forceps delivery)	31	0	1	3
Forceps (labour not induced)	166	3	7	18
Caesarean section	69	3	4	3
Manual removal of placenta	27	1	0	8

Among the 2,266 "booked" cases there were six maternal deaths, and eight such deaths among the 244 emergency cases—a maternal mortality in the first category of 2.64 per 1,000 and in the second of 32.82. The number of cases of premature birth was 160. The lowest weight at

birth of a child who survived was 2 lb. 13 oz., the weight on discharge being 4 lb. 2 oz. Thirty-nine sets of twins were born during the year; seven of the babies died and eight were stillborn. The total number of stillbirths was 137; the stillbirth rate for the "booked" cases was 3.6 per cent. and for the emergency cases 22.1 per cent. In fifty-one cases of trial labour for suspected disproportion one mother died and one baby was stillborn.

Correspondence

Rupture of Extensor Pollicis Tendon

SIR,—In the course of some work on spontaneous rupture of the extensor pollicis longus tendon I have read the letter by Mr. Maurice Lee in your issue of September 29, 1934, page 611. I would warn surgeons against following his advice when he says that should another case present itself he would not hesitate to follow Mr. Andreasen's procedure (*British Medical Journal*, 1934, 2, 515) of suturing the distal end of the ruptured tendon to the tendon of the extensor of the index finger. I have already published in the *Acta Chirurgica Scandinavica* (1921, 55, 177) a report, which was referred to in the Epitome to the *British Medical Journal* of January, 1922 (para. 136), of two cases in which I made an interposition from free transplanted tendon between the two portions of extensor pollicis longus tendon. It is always possible to find the proximal portion. I have taken the tendon graft from the tendon of abductor pollicis longus. The result after seventeen years is still excellent. The procedure of fixing the tendon of the extensor pollicis longus in another muscle is not the method of choice.—I am, etc.,

STEN VON STAPELMOHR, M.D.,
Chief Surgeon, Norrköping Hospital.

Norrköping, Sweden, Sept. 9.

Bilateral Lobar Pneumothorax

SIR,—Dr. Crocket's article in the *Journal* of August 7 and the ensuing correspondence in your columns on bilateral artificial pneumothorax treatment prompt me to put in a plea for a trial in this country of the bilateral lobar pneumothorax employed by Dr. Maurer of Davos in the treatment of bilateral pulmonary tuberculosis.

The technique is described in the April issue of the *British Journal of Tuberculosis*. This modification of bilateral artificial pneumothorax is applicable to cases in which the disease is limited, as it often is, to the upper lobes. The principle of the method is, in brief, that after intrapleural injection of hypertonic glucose solution the sound lower lobes are re-expanded and fixed to the chest wall, an air pocket remaining over each of the affected upper lobes. Induction is not always easy and requires skill and patience, but the after-treatment of an established lobar pneumothorax is straightforward.

Three advantages may be claimed for the method. First, the lower lobes and the mediastinum being fixed, a more effective collapse of the diseased upper lobes can be maintained, refills with an end-pressure of zero being given on both sides. Secondly, as a consequence of the gain in functioning alveolar tissue, the anoxaemia, which is frequently present in bilateral pneumothorax, disappears. Thirdly, as the air pockets are small, any of the complications of artificial pneumothorax—effusion, empyema, or perforation—which may arise will be less dangerous and more easily dealt with than when occurring in bilateral artificial pneumothorax.

During the period of induction constant clinical and radiological observation are necessary, and it should only be undertaken in a hospital or sanatorium. Considerable patience is required. The pleural sheets may not adhere at the first attempt and the intrapleural injection of increasing quantities of glucose solution may have to be repeated two or three times. If a refill is given too soon the visceral pleura is peeled off the chest wall. On the other hand, if delayed too long excessive expansion of the diseased lobe and dissemination into the redeveloped lower lobe or lobes is a theoretically possible complication. It has not been seen in practice and the risk appears to be slight. Professor Brauer in the early days of adhesion cutting saw a considerable number of cases in which the pneumothorax was almost completely let out as a result of post-operative emphysema and lack of a timely refill. He states that he never saw an intrapulmonary dissemination from this cause as long as a small air pocket remained over the affected lobe. The other possible complication is the production of a tuberculous effusion with subsequent obliterative pleurisy. I have seen one case in which a tuberculous pleural effusion developed during the induction, probably as a result of irritation of subpleural tubercles. However, the ensuing obliterative pleurisy was easily checked by appropriate treatment. It should perhaps be mentioned here that there is never any tendency to obliterative pleurisy as a sequel of the transient sterile effusion evoked by the hypertonic solution.

When bilateral lobar pneumothorax has been successfully established the after-management of the case is simple and the results more than compensate for the care required during the induction period. I have had an opportunity of observing these cases over a period of several years, and the improvement in the condition of the patient, after a bilateral artificial pneumothorax has been replaced by a bilateral lobar pneumothorax, is very striking.—I am, etc.,

R. J. C. MAXWELL, M.Ch., F.R.C.S.

London, W.C.1, Sept 16.

Expulsion of Placenta Praevia in Advance of Foetus

SIR,—Being interested in Dr. J. W. Nankivell's Clinical Memorandum on "Expulsion of a Placenta Praevia in Advance of the Foetus" which appeared in the *British Medical Journal* of September 11, I hope you will publish this letter. The condition cannot be so extraordinarily rare as I have had personal contact with two such cases since 1927. In both my cases the entire sac was expelled intact with considerable accompanying antepartum haemorrhage, there being no operative intervention, and in both instances the child lived. I am convinced that many other instances of similar occurrences could be cited but have not been reported in the literature.—I am, etc.,

Dublin, Sept. 13. O'DONEL BROWNE.

Indications for Induction of Abortion

SIR,—May I take advantage of your columns to voice a protest against the attitude held at the moment in some hospitals on the subject of induction of abortion in "suitable cases"? I have had occasion to send two cases to London during the past month, cases in which, in

my opinion, induction of abortion was of first consequence to the patient, and in both the operation has been deemed unnecessary.

The patient in the first case, a woman of 39, has a son of 15, and has been for nine years under treatment for Parkinsonism of such severity that she has difficulty in looking after her house, and is in a state of chronic depression. What further strain the childbirth and its anxieties would impose upon her is difficult to estimate—the woman has already once attempted suicide—and one shudders to think of the mental attitude of an infant brought up in such surroundings. In the second case a woman of 35, with one child of 5, has an arrested tuberculous lesion of the lung. I was informed by the physician who saw her that "with frequent ante-natal supervision and possibly sanatorium treatment the woman would probably go through her confinement successfully."

I am sure that the specialists who saw these cases dealt rightly with them according to the rules of their departments. But I still maintain that induction of abortion was the correct treatment in both cases, and I regret that the personal aspect should have been so completely dwarfed by the clinical.—I am, etc.,

Luton, Sept. 16. EDWARD A. BUTTERWORTH, F.R.C.S.

Sulphanilamide in the Treatment of Gonorrhoeal Infections

SIR,—I, too, felt some surprise at Dr. Anwyl-Davies's, I think too early, decision (*Journal*, September 11, p. 553) that sulphanilamide is useless in the therapy of gonorrhoea. My first trials of prontosil album by mouth, begun a year ago, were on lines similar to those reported by Dr. Anwyl-Davies (who followed the trials of American observers), and led me to think the drug was useless. After increasing the dosage of prontosil, however, and even repeatedly giving one form of it intravenously, I am almost convinced that, once correct dosage and method of administration have been worked out, we shall find in this drug a specific treatment for gonorrhoea in the male which will make the irrigation room but seldom required.

I therefore welcome, and am much encouraged by, the Guy's Clinic observations briefly outlined by Drs. Erskine, Johnson, and Lloyd in their letter on page 598 of your issue for September 18.—I am, etc.,

London, W.1, Sept. 15. H. M. HANSCHELL.

SIR,—The condemnation of sulphanilamide treatment of acute gonococcal infections by Dr. Anwyl-Davies in your issue of September 11, without any suggestive alternative method, leads me to propound my own methods among my private cases. I have not got the advantage of carrying out extensive experimental work among hospital patients, so I must be very certain of my results before advocating any particular line of treatment.

Careful investigation and treatment of sixty cases during the past three years has enabled me to proclaim a cure between the fourth and eighth week, the average being the sixth week. Each of these cases has been followed up by inquiries every six months, and in none has there been any symptom reported suggestive of chronicity.

I have entirely dispensed with wash-outs, either of the urethra or bladder, but I rely upon a strict alkaline diet, urethral instillations of a mercurochrome solution massaged into the bladder, bi-weekly intradermal injections of gonoderm (Parke, Davis and Co.), and daily ultra-short-wave therapy for ten to twenty minutes. Finally, in some of the more severe cases I massage the urethra upon a straight sound and instil gomenoleo, as advocated by Professor Guyon of Paris. Three of my present cases are receiving sulphanilamide in addition to the above-mentioned treatment, but as yet no obvious benefit has been noted.

In none of my cases has any complication occurred, which fact I attribute to ultra-short-wave therapy, and this treatment is advocated by Professor von Litchtenburgh in Budapest. It seems a pity that there is no clinic in this country where poor patients can have the advantage of this method.—I am, etc.,

London, W.1, Sept. 20. MORTON WHITBY.

Nutrition in the Falkland Islands

SIR,—I have read the letter of Dr. G. Arbour Stephens in your issue of September 18 (p. 600) and the article of Dr. Cheverton (*Journal*, January 16, 1937) which prompted it. Concerning the latter, I would remark that I am by no means convinced that all the illnesses labelled "influenza" are in fact influenza. As our knowledge of virus diseases is extended it is not impossible that the term will be found to cover more than one pathological entity.

I would submit that Dr. Stephens has been misled in the course of his inquiries. He says: "Vegetables, which are so essential . . . for growing children, cannot be grown, or, if so, with great difficulty, as the weather, with so little sunshine and so much damp, does not allow of such vegetation." First of all, I would like to quote from the diary of Bernard Penrose, surgeon's mate of the armed shallop *Penguin*, which reoccupied the Falklands after the affair with the Spaniards in 1769 (which was responsible for Nelson going to sea). He says:

"But the glory of our colony was the gardens which we cultivated with the greatest care, as being fully convinced how much the comforts of our situation depended on being plentifully supplied with vegetables. . . . The soil was fine black earthy, rather shallow . . . the manure we made use of was decayed sea-weed, and this we found for the time we had to stay answered our purpose very efficiently. . . . We were plentifully supplied with potatoes, broccoli, cabbages, carrots, turnips, borecole, spinnage, parsley, lettuce, English celery, mustard, cresses, and some few but very fine cauliflowers. . . ."[1]

I was only in the Falkland Islands for a short stay, a matter of six years. During that time I grew, and so did every settlement and shepherd, ample supplies of potatoes, carrots, peas, broad beans, cabbages, kale, turnips, lettuces, beetroot, radishes, and onions. These seem to me to be quite adequate for the needs of growing children. It is nonsense to say that vegetables cannot be grown.

Again: "Malnutrition is a basic factor in the human beings, cattle, and sheep of the Falkland Islands." I would remind Dr. Stephens that the staple industries of the Falkland Islands (on land) are sheep and cattle farming. They would not be a very prosperous community if the inhabitants and the animals they raise were suffering from malnutrition. If Dr. Stephens were to visit the Falklands he would discover that both the cattle (Devons, Herefords, a few Jerseys, and Highland—all grass-fed) and sheep provide excellent beef and mutton. (Cf. the price fetched by Falkland Island wool in the open London market.) The cattle are fat, fertile, and splendid milkers. I question whether there are any in the world to beat the grass-fed island-bred horses for endurance. As for the people, they are as hardy as the

[1] *Account of the Last Expedition to the Falkland Islands.* By Bernard Penrose, Surgeon's Mate (*circa* 1772). British Museum Library.

animals, or they would not be able to do the work necessary for sheep- and cattle-farming.

"Such a state of soil combined with limited sunshine is responsible for a poor state of health amongst the children, whose resistance to gastric (*sic*) and respiratory disease is very low." *I can scarcely refrain from rubbing my eyes!* As I have already mentioned, I was only there for a brief period, but I have rarely met a hardier set of youngsters than Falkland Island children. During my short stay I saw no sign of "low resistance to gastric and respiratory disease." Had Dr. Stephens mentioned allergy, I would have agreed that the colony is a field worth special investigation. Asthma is met with very frequently not only in the island-born but also in those who have gone out from this country. Possibly the large amount of mutton in the diet may be responsible.

"During the last two years as many as thirty operations for appendicitis have been performed." In the six years of my experience I only saw or heard of one case of appendicitis. That variations in the incidence of this disease occur is well known. The history of its rise in the French Army following the introduction of enamelled cooking utensils and its fall when these were withdrawn is a case in point. I refrain from further comment.

Dr. Stephens then goes on to say:

> "Under present conditions it is impossible (!) for the islanders to be properly fed and to be A1 people. If Great Britain is to possess colonies, then it must be on the condition that the colonists are able to lead good, strong healthy lives, or, in other words, no colony should be retained at the expense of the community and especially of the children. . . . The problem for us in Great Britain, and especially for the medical profession, is . . . are we to allow the breeding of *fragile children for the sake of retaining a colony?*"

This all sounds very high-souled and may do credit to Dr. Stephens's heart—at the cost, I fear, of serious reflections on his head. What does he recommend as a solution? He makes general statements of principle, in effect; that in any of our possessions where conditions of health do not reach what he considers to be a necessary standard we should abandon the places. This would also entail abandoning the inhabitants. What would happen, for instance, in the case of our tropical and subtropical possessions where malaria, dysentery, plague, and cholera are endemic, to mention only a few diseases. Would he be in favour of handing them over to other masters?

We can leave the Falkland Islands out of the question, for Dr. Stephens's statements concerning them are so grossly inaccurate as to be not only amusing but ridiculous. In fact I cannot help wondering whether somebody has been wilfully misleading him. But what about India? West Africa? Rhodesia? the West Indies? Must we just "dump" the "White Man's Burden" and leave our less fortunate fellow-subjects to their own devices? It may be that sources of information are open to Dr. Stephens which are denied to others. So far as my own opinion of the Falkland Islands is concerned it would not be easy to find a healthier, happier, or more prosperous community within the Empire. I am sure he would be interested if he were to inspect the statistics of the Government Savings Bank in the Falkland Islands. He may be interested to know, although he does not quote actual sunshine records, that after two hours' exposure to the sun in Fox Bay, West Falkland, all the skin peeled from my back, and that I still carry freckles on my arms which appeared when riding with my sleeves rolled up.—I am, etc.,

Ashtead, Surrey, Sept. 19. H. M. STANLEY TURNER, Wing Commander, R.A.F.

SIR,—Having spent two very enjoyable years in the West Falkland Island I find myself unable to agree with Dr. Stephens (*Journal*, September 18, p. 600), and I should like to detail my reasons for disagreeing.

1. With a little extra care the following vegetables were grown in my own garden: cabbage, kale, broccoli, kohl-rabi, lettuce, carrots, swedes, turnips, and parsnips. Better gardeners also produced beans and peas; gooseberries, currants, and raspberries flourished with care. The West Islanders admittedly did not grow these vegetables as a rule. They had, however, every opportunity of doing so, but were not fond of gardens and did not miss the produce.

2. The land is acid in the same way that any undrained piece of moorland is acid. One or two deep trenches correct this, and the addition of a little basic slag turns such soil into moderate garden soil. Basic slag or lime could be purchased locally. Usually seeds required regular watering until they had developed deep roots, as the wind dried the surface of the soil very rapidly. Established plants only required shelter from the wind.

3. There is one wood, planted some years ago, on the West Island in which the trees look quite English. This I accept as evidence that trees can be grown by those who understand their culture. The inhabitants as a whole do not like trees.

4. The health of the West Islanders during my stay was well above that of an average population here. Admittedly the teeth were poor, but they took little care of them, and their ideas of infant feeding were not calculated to help the growth of healthy teeth. I understand that there was some shortage of milk in Port Stanley, but this was not the case in the west. It was fashionable to have the appendix out, and I suspect that few of the cases operated on were of the acute type. Fresh infections spread rapidly, as they always do among people unaccustomed to disease. Infections brought by ships were of differing strains, and the inhabitants never acquired an immunity to them, I submit for this reason.

Bearing these facts in mind I feel that the Colonial Office has done all that is necessary for the health of the Falkland Islands, and I fail to see that a Royal Commission can help a colony where people prefer to eat bread and mutton rather than to take the trouble of keeping a garden.—I am, etc.,

T. P. BINNS, Formerly Medical Officer, West Falkland Island.

Shirebrook, Notts, Sept. 18.

Quinine Tolerance and Hyperthyroidism

SIR,—Everyone must have been struck with the great *differences in the amount of quinine* that can be given to patients before symptoms of cinchonism appear. I am not referring to cases of idiosyncrasy to the drug, but to intolerance to continued administration.

It has appeared to me that cinchonism is most easily induced in persons with hypothyroidism, whereas, when excessive thyroid activity is present, much larger amounts can be given. Further, in frank cases of hyperthyroidism large doses of quinine, given for weeks or months, appear to modify the symptoms and signs without producing cinchonism. Indeed, occasionally, cure seems to follow such treatment.

The suggestion I am making is that the determination of quinine tolerance might be a useful method of revealing slight hyperthyroidism.—I am, etc.,

London, W.1, Sept. 20. A. FINEY.

Ether Convulsions

SIR,—Having read with interest the letter from Mr. Matthews and Dr. Geal in your issue of September 11 (p. 559) concerning a case of ether convulsions, I should like to describe a case which occurred while under my care a few weeks ago.

The patient was a boy, aged 7, who was admitted to hospital at night as an emergency with osteomyelitis of the femur. He had a temperature of 103° and a pulse rate of 138. It was not a particularly hot night and the temperature of the theatre was not over 70°. Premedication consisted of atropine 1/150 grain. The patient was induced with gas and oxygen administered with a Boyle apparatus followed by gas, oxygen, and ether which had been taken from a fresh bottle.

The operation proceeded uneventfully until the drill was used to open the femur. The child's respirations then began getting irregular, and there was slight twitching of the face which was immediately followed by convulsions. Respiration became spasmodic, the child was blue, and the pulse was imperceptible. Oxygen and carbon dioxide were administered at once and 1.7 c.cm. of coramine. With much difficulty 2 c.cm. of evipan was given intravenously. The convulsions stopped and the pulse improved slightly.

The operation was completed without any further anaesthetic. Although the convulsions ceased the child went into tetanic spasms, which recurred every few minutes. The hands took up the typical "accoucheur's position," the ankles were dorsiflexed, and the toes flexed. During the spasm, which lasted about a minute, the child became pulseless; between the spasms the pulse was rapid and thready. The patient was returned to bed when 5 c.cm. of calcium gluconate was administered intramuscularly and rectal saline given. The spasms gradually became less until they ceased completely, about two hours after the completion of the operation. The child died ten days later from the primary infection. Chloroform was not administered as the condition of the heart was so poor that this might have further endangered the life of the patient.

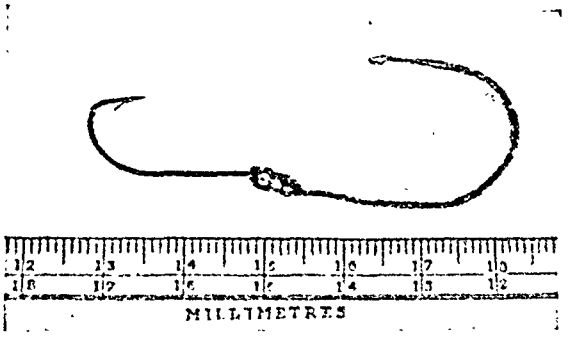
I have never previously heard of a case of tetany following ether convulsions. It seems to me that this case tends to support the theory that ether convulsions are due to the diminished active fraction of the serum-calcium, which leads to neuromuscular irritability.—I am, etc.,

London, W.1, Sept. 13 A. OPENHEIM, D.A.

Aetiology of Erythema Nodosum

SIR,—In 1902 a young girl, aged 26, came into my ward at the Prince Alfred Hospital, Sydney, with the diagnosis of rheumatic fever by three doctors. Her pulse was 120 and her temperature 99.8°–100°. Her weight was 7 st. 12 lb. Both ankles and left wrist were swollen and showed typical erythema nodosum. Her brother had died of Addison's disease. After rest the temperature fell below 99°. I then tested her with tuberculin; she was very sensitive: indeed, a dose once raised the temperature over 104°. She was treated with tuberculin alt (T.A.) alone. After treatment the joints became normal again. Her weight increased to 9 st. 10½ lb; the erythema nodosum vanished, and six years later she was quite well. Salicylates had failed—tuberculin succeeded.

At that period the great dermatologists Radcliffe Crocker (my teacher) and Hector Mackenzie considered erythema nodosum to be a *rheumatic* lesion. Even in 1920 Osler wrote in his great textbook: "Erythema nodosum. . . . Some regard it as a symptom of tuberculosis, but clinically we rarely see any definite association." I am not a genius, as Sir William Osler certainly was, but I can declare that I have never seen erythema nodosum except in tuberculosis; and in my experience erythema nodosum always reacts to tuberculin in diagnostic doses and clears up rapidly with therapeutic doses of tuberculin. I cannot imagine that any English dermatologist who uses tuberculin doubts that erythema nodosum is a tuberculous lesion and nothing else. At any rate in my experience erythema nodosum is never a rheumatic lesion, nor caused by haemolytic streptococci.—I am, etc.,



W. CAMAC WILKINSON, M.D.Lond.

London, W.1, Sept. 20.

Foreign Body in Rectum

SIR,—I was recently interested in treating a costermonger, aged 60, who attended here having had fifteen hours of rectal discomfort and desire to defaecate with no relief. Two days previously he had eaten several jellied eels.

On physical examination I discovered a piece of cheap fishing line protruding ex ano with no evidence of haemorrhage. In his anal canal this passed upwards to a fish-hook, one inch long, which lay with its hackle pointing inferiorly and its barb lightly caught in one of the valves

of Ball. When pushed upwards, and partially enclosed in the crook of my examining finger, I was able to deliver it without much pain or trauma.

Though openly congratulating the old man on a magnificent escape, I viewed the two possible causes of the presence of this "ectopic" fish-hook with wonder: (1) If inserted anally, it was an extraordinary weapon for use in anal eroticism, etc. (2) If it journeyed downwards with the eels' remains, what an amazing freedom for a hook which is designed efficiently and quickly to pierce mucous membrane.—I am, etc.,

London Hospital, E., Sept. 12. C. P. WARREN.

Parathyroid Extract and Enlarged Prostate

SIR,—In answer to Dr. F. O. Taylor's and several personal letters I wish to express regret at being so vague in the statement I made on the cure of enlarged prostate by parathyroid extract (*Journal*, August 21, p. 402). I learnt of the treatment from Dr. Wood when on holiday, and have been unable to get in touch with him since. True it was only a solitary case, but the result was so dramatic that I was anxious to hear if any of your readers knew the rationale of it. The parathyroid preparation used was Parke Davis extract 1/10 grain, equivalent to 1 grain—not 1/2 grain as previously stated—of fresh gland, given orally.—I am, etc.,

London, W.1, Sept. 17. A. P. BERTWISTLE.

Safe Milk

SIR,—Is it not time that responsible publications like a Government White Paper or a *Times* leading article ceased to mislead the public by speaking of "clean" milk when what matters is "safe" milk? The householder is thereby taught to think that if visible cleanliness is practised in what he sees of farm or dairy premises, and if his milk bottle is duly labelled "accredited," then he is safe. Enteric or tuberculosis bacilli may lurk in thousands, but they are unseen. Why are we always afraid to grasp the nettle? It is safety, not cleanliness, that really matters, and when the *Times* (September 17) says "clean milk is more attractive than dirty milk" it reassures a public that knows its milk supply is clean aesthetically and thinks therefore it is safe.—I am, etc.,

Peppard Common, Oxon, Sept. 20. ESTHER CARLING.

Importance of Post-mortem Examinations in Inquest Cases

SIR,—Some difficulty may be experienced in obtaining post-mortem examinations in inquest cases admitted to hospital because the coroner may exercise his right to refuse to grant them when asked to do so by house officers. The reasons for this, I believe, are twofold. First a desire to save the pocket of the taxpayer, and, secondly, a view that young house officers who might be over-anxious to obtain post-mortem examinations in this sort of case in order to obtain the two or three guineas which such an examination allows them should be discouraged from so doing. The latter view, which is resented by house officers, is usually quite unjustified, as they are instructed to apply to the coroner for a post-mortem by the honorary medical staff in all cases of road accident deaths or other deaths where there has been any doubt as to the probable cause of death. A refusal to allow these examinations places considerable difficulties in the way of the medical witness who is called upon to state in his opinion the cause of death at the inquest, and, in addition, it has led on more than one occasion to the return of a wrong verdict.

I have in mind, in particular, two cases, one of a young soldier who, at the local barracks, jumped over a horse whilst performing gymnastic exercises, and complained of transient pain in the back part of his neck. He was later admitted to hospital in an unconscious condition, and an *x*-ray examination revealed what at the time was thought to be a fracture of the cervical spine. He subsequently died, and the house-surgeon, on my instructions, asked for a post-mortem examination, which was refused. There were some very puzzling points about the case, one of which was a persistent hyperpyrexia. At the inquest the house-surgeon said that he could not state what the cause of death was unless a post-mortem examination was allowed. The coroner, however, overruled him and said that he was satisfied that the cause of death was accidental, due to a fracture of the cervical spine, and this verdict was returned. It subsequently transpired that another junior house-surgeon interested in the case, and not appreciating that it was an inquest one, had obtained permission from the relatives and had performed a post-mortem examination, which revealed that the so-called fracture of the cervical spine was only a congenital abnormality, and that the man had a number of small aneurysms on the circle of Willis, one of which had ruptured, giving rise to a haemorrhage, which had extended down into the region of the pons. The inaccurate verdict in this case was not a serious matter, but it is possible that the man could have ruptured an aneurysm such as this while sneezing, or even spontaneously.

The second case was one in which a man of 60 was cycling across some cross-roads and was hit by a car, turned a somersault twice in the air, landing on his head. He was brought to hospital suffering with concussion and injury to the chest. A radiograph of the chest failed to reveal any fractured ribs, but signs of fluid in the chest developed and nearly a pint of blood was aspirated from one side. The chest again filled up with blood and the old man developed signs of cardiac failure and died. A post-mortem examination was requested by the house-surgeon, but again the coroner refused to grant it, and at the inquest a verdict of death from natural causes was returned, although there was no evidence whatever of previous ill-health.

In the provinces coroners are often lawyers without medical knowledge. It is surprising that a verdict of death from natural causes could be returned in the case of a man who had been knocked down by a car, admitted to hospital with concussion, and in whom a haemothorax was present. There was not the slightest doubt in the minds of all the doctors who saw this case that his death was entirely due to the accident. I am using the publicity of your columns to voice a feeling that radical changes are needed in a system which may allow a coroner without medical knowledge to adopt the role of philanthropist and thus render more difficult the doctor's task, which is often difficult enough, of stating the probable cause of death. I would put forward a strong plea that post-mortem examinations should be available in inquest cases if the doctor in charge of the case so desires, or as an alternative that post-mortem examinations be compulsory in all inquest cases.—I am, etc.,

R. BROOKE, M.S., F.R.C.S.,
Honorary Surgeon, Royal West Sussex Hospital.

West Worthing, Sept. 10.

Homes for Cancer Patients

SIR,—I was recently shown a copy of a pamphlet setting forth the aims of a charity called "County Homes for Cancer." Neither I nor any colleagues I questioned had been circularized, although the appeal had found its way into at least one newspaper office.

I understand that a public appeal for funds on behalf of the charity is in active progress. In view of the fact that the policy of the homes is to establish wooden hutments in each county in which cancer patients may be observed and treated until the end, would it not be a wise preliminary to an appeal to seek the views of the medical profession as to the best type of building for such a purpose, and the probable cost of installing such expensive yet essential items as radium and deep *x*-ray therapy apparatus in every county, where they may well duplicate existing equipment in established institutions?—I am, etc.,

London, W.1, Sept. 18. HAMISH WALLACE.

Provincial Diabetic Clinics

SIR,—The Diabetic Association would be glad to publish in its journal particulars of diabetic clinics which are held in the provinces. This information is frequently asked for by diabetics who live outside London and wish to attend a clinic. We should be very grateful if readers would send particulars of such clinics to the secretary, the Diabetic Association, 124, Baker Street, London, W.1.—I am, etc.,

STELLA CHURCHILL,
Hon. Secretary, Medical Committee.

Sept. 14.

Obituary

DE BURGH BIRCH, C.B., M.D.,

Emeritus Professor of Physiology, Leeds University

The death took place in a nursing home at Bournemouth on September 18 of Dr. de Burgh Birch, who was professor of physiology in the University of Leeds from 1883 to 1917, and dean of the faculty of medicine for eleven years.

The son of de Burgh Birch, M.D., of the Madras Medical Service, he was born on May 18, 1852, and was educated at Hofwyl, Switzerland, at Manilla Hall, Clifton, and at the Bristol Medical School and General Hospital, proceeding to the University of Edinburgh in 1874 and graduating there as M.B. and C.M. in 1877. Then at the end of three years as assistant to the Professor of Institutes of Medicine he took the M.D., gaining the gold medal, and was elected a Fellow of the Royal Society of Edinburgh. On his retirement from the service of the University of Leeds in 1917, after thirty-four years as a teacher, he was given the title of Emeritus Professor.

Professor Birch was for many years a member of the British Medical Association, which he joined in 1883 on his appointment as the first full-time professor of physiology at Leeds. He was a vice-president of the Section of Pathology and Bacteriology at the Annual Meeting at Leeds in 1889, and vice-president of the Section of Physiology at Bristol in 1895. He had long held a commission as a medical officer in the old Volunteer Force, and for these services was created C.B. in 1909; he also received the Volunteer Officers' Decoration. For two years during the war he was A.D.M.S. to the 62nd (West Riding) Territorial Division.

ANDREW H. WATT, M.B., F.R.C.S.ED.,

Consulting Physician, Johannesburg Hospital

We regret to announce the death on September 3, at Auckland Park, Johannesburg, of Dr. Andrew Watt, who was well known in South Africa as a physician and radiologist and as an authority on silicosis. He gave up consulting practice some years ago to become chief medical officer to the Rand Mutual Assurance Company.

Andrew Hutton Watt, a Scotsman by birth and parentage, was born in 1871, and from the Royal High School went to study medicine at Edinburgh University. He graduated M.B., C.M., with honours, in 1897, and took the F.R.C.S.Ed. in 1899 after holding resident posts at the Royal Infirmary and the Royal Hospital for Sick Children. During the Boer War he served as a civil surgeon, and returned to South Africa after the declaration of peace, gradually building up a high reputation as an expert in the accidents and diseases of the gold-mining population of the Rand. He was for some years physician to the miners' phthisis sanatorium at Springkell, and then settled in Johannesburg as a consulting physician and radiologist. He was the author, with L. G. Irvine, J. P. Johnson, and W. Steuart, of *Silicosis (Miners' Phthisis) on the Witwatersrand.* On retiring from the active medical staff of the Johannesburg Hospital he was elected honorary consulting physician.

Dr. Watt joined the British Medical Association in 1898 as a member of the Johannesburg Division. He was president of the Witwatersrand Branch in 1926–7 and a member of the Federal Council. In 1932 he was appointed a member of the South African Medical Council, through which body his deep knowledge of industrial disease and insurance problems was always at the disposal of the Union Government.

GEORGE H. SIMMONS, M.D.

Dr. Alfred Cox writes:

May I add a few words to your feeling tribute to my old friend? For many years he was, in a way, my *opposite number*, for though he resigned the secretaryship of the A.M.A. in 1911, as general manager he kept an alert eye on all medical affairs inside and outside the United States. I was introduced to him on one of his visits by my then chief, Whitaker, and a friendship grew up between us which was greatly strengthened by many letters I had from him. He took a great interest in our insurance struggle and favoured me with his views on our tactics—views which were always shrewd. But his chief characteristic was the one on which your obituary notice laid stress—his ability to look at affairs in a detached and dispassionate way. This was very valuable to his friends, for I need hardly say that at the time of the fight none of us was able thus to regard affairs.

In all the crucial periods of the British Medical Association's work during my time I could always depend on his interest and on his advice—spontaneously offered, for he was an assiduous reader of our *Journal.* Though a patriotic American he was proud of his English birth and loved the scenes of his youth, to which he often returned, never without paying a visit to B.M.A. House. His modesty and self-effacement, to which you have justly paid tribute, concealed immense energy and a very sound judgement. He was indeed a "grand old man," for age never dimmed his interest in his life's work.

Dr. JAMES FORSYTH FALCONER, who died suddenly at Hastings on September 12, was born at Elgin in 1875, the son of James Leslie Falconer. He was educated at Elgin Academy and the University of Edinburgh, and took the M.B. and Ch.B. degrees in 1898 and the certificate in medical psychology in the following year. His first appointments were those of house-physician to the Royal Hospital for Sick Children, Edinburgh, house-surgeon to the Glasgow Royal Infirmary, and assistant physician to the Edinburgh Fever Hospital. He was then for some years assistant surgeon and ophthalmic surgeon to the North Ormesby Hospital, Middlesbrough, before settling in Brixham, where he became medical officer of health, Admiralty surgeon, medical officer to the child welfare centres, visiting surgeon to the Seamen's Orphanage, and surgeon to the Brixham Hospital. Dr. Falconer joined the British Medical Association in 1900 and had held office as chairman of the Cleveland Division, Representative at the Annual Meeting in 1919, and a member of the Scrutiny Subcommittee of 1919–20.

Universities and Colleges

UNIVERSITY OF LONDON

A course of three lectures on "Social and Geographical Pathology of Cancer and Tuberculosis" will be given by Dr. Georg Wolff, formerly Director of the Section of Medical Statistics in the Public Health Department of the City of Berlin and Privat-Dozent in the University, at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C., on October 4, 5, and 6, at 5.30 p.m. The chair at the first lecture will be taken by Sir Ernest Graham-Little. Admission to the lectures is free, without ticket.

The Services

Colonel W. E. R. Williams, O.B.E., I.M.S., has been appointed Honorary Surgeon to the Viceroy and Governor-General of India.

COMMISSIONS IN THE R.A.M.C.

The War Office announces that applications are invited from medical men for appointment to commissions in the Royal Army Medical Corps. Candidates will be selected for commissions without competitive examination, and will be required to present themselves in London for interview and physical examination on or about October 21, 1937. They must be registered under the Medical Acts, and normally must not over the age of 28 years.

Successful candidates will in the first instance be given short-service commissions for five years. During the fourth year of this period they will be given the opportunity of applying for a permanent commission. Those not selected will retire on completion of five years' service with a gratuity of £1,000.

Full particulars of the conditions of service and emoluments, also forms of application, may be obtained on application, either by letter or in person, to the Assistant Director-General, Army Medical Services, the War Office, London, S.W.1.

Medical News

The annual dinner of past and present students of University College Hospital will be held in the library of the Medical School, University Street, W.C., on Friday, October 8, at 7 for 7.30 p.m., when the chair will be taken by Dr. W. F. Addey. Applications for tickets, accompanied by remittances (tickets 12s. 6d. each, not including wines), should be made not later than October 7 to the dinner secretary, University College Hospital Medical School, University Street, W.C.

The annual dinner of the University College Hospital Medical Women's Association will be held at the Langham Hotel, Portland Place, on Friday, October 8, at 7.30 for 8 p.m., when the chair will be taken by the president, Dr. Freda Kelly. Members intending to be present should notify Dr. A. L. Winner, 4K, Portman Mansions, Baker Street, W.1, before October 5.

The annual dinner of the Middlesex Hospital Medical School will be held at the Savoy Hotel on Friday, October 1, at 7.30 p.m., with Dr. Douglas McAlpine in the chair.

The annual old students' dinner of St. Thomas's Hospital will be held at the Dorchester Hotel, Park Lane, on Friday, October 8, at 7.15 for 7.45 p.m., with Dr. J. S. Fairbairn in the chair.

The annual dinner of past and present students of St. Mary's Hospital Medical School will be held at Claridge's on Saturday, October 2, at 7.30 p.m., with Mr. V. Zachary Cope in the chair.

A course on recent advances in the knowledge of infectious diseases of children will be held at the University Children's Clinic of the Charité Hôpital, Berlin, under the direction of Professor Bessau, from October 18 to 23. In addition to the ordinary infectious diseases of childhood, rheumatic infection, meningitis, poliomyelitis, encephalitis, pneumonia, tuberculosis, and syphilis will be discussed. The fee is RM. 50. Further information can be obtained from the Berliner Akademie für ärtzliche Fortbildung, Robert Koch-Platz 7, Berlin, N.W.7.

Lord Horder will give an address at the opening session of the Third National Coal Convention, which is to be held at Harrogate on October 6 and 7.

A sessional meeting of the Royal Sanitary Institute will be held in conjunction with the Welsh Branch of the Society of Medical Officers of Health and the North Wales Centre of the Sanitary Inspectors' Association in Llandudno Town Hall on Friday, October 1, at 4 p.m., when there will be discussions on "Tuberculosis in Wales: A Stocktaking," to be opened by Dr. D. A. Powell, and "The Conway Mussel Purification Tanks," to be opened by Dr. R. W. Dodgson. Dr. D. E. Parry Pritchard will read a paper on "Notes on a Recent Outbreak of Bacillary Dysentery."

The French League against Rheumatism will hold its annual meeting in Paris on October 9, when there will be a clinical meeting in the morning at the Hôpital Saint-Antoine and a meeting at the Faculty of Medicine in the afternoon. Further information can be obtained from the Permanence de la Journée du Rhumatisme, 23, Rue du Cherche-Midi, Paris, 6e.

The annual meeting of the French Society of Oto-rhino-laryngology will be held in Paris under the presidency of Professor Brémond of Marseilles from October 18 to 21, when the subjects for discussion will be intracranial surgery of the auditory nerve by Drs. Aubry and Ombrédanne, and acute inflammation of the larynx by Drs. Le Mée, André Bloch, and Bouchet. Further information can be obtained from the general secretary, M. Henri Flurin, 19, Avenue Mac-Mahon, Paris, 17e.

A series of ceremonies and lectures and an exhibition will be held at Prague, Brno, and Bratislava from September 24 to 28 to commemorate the one hundred and fiftieth anniversary of the birth of the celebrated histologist J. E. Purkinje.

On the occasion of the annual Buckston Browne Dinner on November 11 it is proposed to hold an exhibition of works of art by Fellows and Members of the Royal College of Surgeons of England, which will remain open for about three weeks and will be held in one of the Museum Rooms at the College. Any Fellow or Member wishing to exhibit some of his work, either pictorial or sculptural, is asked to communicate with Dr. John Beattie, Royal College of Surgeons, Lincoln's Inn Fields, W.C.2, as soon as possible.

The International Congress of Hepatic Insufficiency was opened formally at Vichy on September 16 by M. Marc Rucart, French Minister of Public Health, who arrived at the spa on September 15 to open a new third-class bathing establishment. Dr. Hamilton Fairley spoke on behalf of the British delegation at the opening session, and Dr. Anthony Bassler was spokesman for the American delegation. At the request of M. Rucart a minute of silence was observed in tribute to the late President Masaryk just before the Czechoslovakian delegate, Professor Josef Pelnar, spoke. Among the other specialists representing their countries on this occasion were: Professor Michele Bufano, director of the Medical Clinic of the Faculty of Medicine of Sassari, Italy; Professor R. Brunel Hawes of the Faculty of Medicine of Singapore; Professor Alfred Mousseau of Montreal; Professor W. H. Craib, Head of the Department of Medicine of Johannesburg; Professor Dimitrije Antitech of the Faculty of Medicine of Belgrade; and Professor Soliman Azmi Pacha of the Cairo Faculty of Medicine.

A Peter Pan children's party in aid of the reconstruction fund of the Hospital for Sick Children, Great Ormond Street, is being given by the Lord Mayor and Lady Mayoress at the Mansion House on Thursday, September 30. Queen Mary and the Princess Royal have consented to attend, and Queen Mary will receive purses.

The Earl of Derby will open the new extensions to Evans's Biological Institute, Runcorn, on the afternoon of Thursday, October 7.

The Mayor of Southwark is opening the new Health Services Department of the borough in Walworth Road to-day, Saturday, September 25, at 3.30 p.m.

The annual Motor Exhibition will be held this year for the first time at Earl's Court, London, from October 14 to 23.

Sir Kingsley Wood, the Minister of Health, visited the Tyneside district on Tuesday and Wednesday of this week, and Carlisle on Thursday. On Monday he was the guest of the Lord Mayor at the Mansion House at Newcastle. After addressing representatives of local authorities at the Newcastle County Hall he inspected the work of local authorities at Wallsend, Jarrow, Hebburn, Felling, and Gateshead. On Wednesday morning he visited hospitals, housing estates, and other institutions in Newcastle, and in the afternoon opened the municipal clinic at South Shields.

With the September issue the *Journal of the Institute of Hygiene* ceases to appear as a separate publication and becomes merged with the *Journal of State Medicine*. The new journal will appear on October 1 under the title of the *Journal of the Royal Institute of Public Health and Hygiene*.

September 30 marks the fiftieth anniversary of the death of the famous German surgeon, Bernhard von Langenbeck, the founder of the German Society of Surgery.

The death is announced of Mr. A. P. Molteno, who in 1919, with his wife, made a gift of £36,000 for building and equipping the Molteno Institute for Research in Parasitology and Biology at Cambridge. The institute, under the direction of Professor G. H. F. Nuttall, F.R.S., was opened at the end of 1921 by Lord Buxton, late Governor-General of South Africa.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House, Tavistock Square, W.C.1.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are
EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*
SECRETARY, *Mediseera Westcent, London.*

The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh;* telephone: 24361 Edinburgh), and of the Office of the Irish Free State Medical Union (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin;* telephone 62550 Dublin).

QUERIES AND ANSWERS

A.P.T. with Anti-diphtheritic Serum

Dr. W. L. ENGLISH writes: We get a number of throats which clear up immediately with 4,000 units of serum (anti-diphtheritic). How far is it legitimate to give a dose of A.P.T. at the same time as the prophylactic dose of serum?

Buccal and Lingual Ulcers

Dr. ALICE JOHNSON (Wimbledon, S.W.19) writes: In answer to "Puzzled" (*Journal*, September 11, p. 564), I have found Chesebrough's mentholated vaseline spread over the ulcer two or three times a day of great use.

Dr. L. FORMAN (London, W.1) writes: Recurrent painful ulcers of the mouth have been described in association with agranulocytosis, which may occur spontaneously, or with the periods, or may be produced by a drug containing pyramidon. To detect rhythmical agranulocytosis it is necessary to examine the blood one or two days before the period is due. Erythema multiforme of the mouth also produces blisters which rupture, leaving superficial ulcers. In some cases small doses of streptococcal vaccine given intradermally—for example, 2 millions at weekly intervals—may be useful.

Mr. CHARLES E. SALTER (Exmouth) writes: I have found ultimate relief in this troublesome condition by giving thyromang (gr. 1/2 and gr. 1/8) bipalatinoids (Oppenheimer) night and morning, preceded by half a tumbler of water and followed by a whole tumbler in fifteen minutes, for two to three months continuously.

Medical Treatment for Dupuytren's Contracture

"NADAUD" asks what treatment he can offer to a "small" patient for Dupuytren's contracture other than operation, and whether fibrolysin and iodolysin fulfilled their early promise.

Ultra-violet Irradiation

Dr. F. HOWARD HUMPHRIS writes: The points raised in this question (*Journal*, August 28, p. 438) cannot be answered satisfactorily in a few lines. Ultra-violet light has been used extensively for the treatment of health and for the maintenance of it. Properly administered it is likely to be of great assistance to those who are run down and overworked, but otherwise in normal health. There is no objection to its frequent use over a period of years provided dosage is more or less accurate and it is administered at properly spaced intervals. "Ultra-violet" should consult one of the many books on the subject.

Cancrum Oris

Dr. J. B. C. MADGE (Shipton Thorpe, York) writes with reference to the letter on cancrum oris in the *Journal* of August 28 (p. 438): Similar lesions are often caused by yaws or bubas, which is protean in its manifestations. Bishop Bere of the Umka Mission wrote a poem in 1888 on the subject.

LETTERS, NOTES, ETC.

"Rheumatic" and "Rheumatism"

Sir FRANK FOX, Secretary of the Empire Rheumatism Council, writes from London: Dr. George S. Banks of Aberdeen (*Journal*, August 7, p. 306) is to be congratulated on his zeal for the purity of the English language. He will be pleased to note that the Empire Rheumatism Council is not guilty of the error to which he calls attention; its title is *not* Empire Rheumatic Council.

Anti-dazzle Regulations

Readers are reminded that under the Road Vehicles Lighting Regulations, 1936, the new anti-dazzle regulations made by the Minister of Transport in April, 1936, come into force on October 3, from which date no head lamp may be used on any vehicle unless the beam of light emitted therefrom is either (1) permanently deflected downwards; (2) capable of being deflected downwards, or both downwards and to the left, at the will of the driver; (3) extinguishable by a device which substitutes a dipped light; or (4) extinguishable by a device which at the same time either deflects the beam of light from another lamp downwards, or both downwards and to the left, in such a manner as to render it incapable of dazzling at a distance of twenty-five feet any person whose eye level is not less than 3 feet 6 inches from the ground. The regulation does not apply to any head lamp fitted with an electric bulb if the power of the bulb does not exceed 7 watts and the lamp is fitted with frosted glass or other material which has the effect of diffusing the light.

Action of Meat Extracts

Dr. A. CRAWFORD (Bermondsey, S.E.) writes: The report of Dr. Boon's work on the action of meat extract in the *Journal* of August 28 (p. 412) is interesting. In view of his finding that meat extract increases the hydrochloric acid and that beef powder was the only substance examined to stimulate the excretion of pepsin, one wonders if a cold expressed beef juice, which contains coagulable protein and meat extractives, has the effect of increasing both hydrochloric acid and pepsin. I find that vague dyspepsias of the atonic fermentative type improve when a little beef juice is taken immediately before meals.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

231 The Haemolytic Constitution

M. GÄNSSLEN (*Klin. Forth.*, 1937, 4, 4, p. 607, and 5, p. 641) regards familial haemolytic icterus (acholuric jaundice, chronic splenomegalic haemolytic jaundice) as a clinical manifestation of a haemolytic constitution. This is always hereditary, its so-called acquired forms being examples of unrecognized infectious or toxic maladies; it is closely connected with other constitutional abnormalities. The essential feature is an abnormal fragility of the erythrocytes, which are convex (hence the name "spherical-cell disease," which Gänsslen uses). They are present in 90 per cent. of cases of anisomicrocytosis, combining an average diminution in diameter of from 8 to 6 or 7 μ with an increase of volume from about 88 μ^3 to 90 to 115 μ^3. The life of the spherical red cells has been computed by Heilmeyer as fourteen instead of 100 to 150 days. They undergo haemolysis in 0.44 to 0.7 per cent. saline solution, while normal erythrocytes resist 0.9 per cent.—the 10 per cent. of cases in which fragility is not or is little increased are explained by an exceptional increase of reticulocytes. Anaemia is often not pronounced, and the index is commonly from 40 to 70 per cent. of haemoglobin: the spleen is palpable in 70 per cent. of cases; the serum bilirubin is increased, and the urine, usually containing urobilin or urobilinogen, with bilirubin and bile acids during exacerbations or gall-stone attacks, is brownish red and has a brick-red fine sediment. It is these symptoms which more often than jaundice lead adult patients to seek medical advice. Jaundice is notably of varying intensity. Among the signs which Gänsslen mentions as constitutional anomalies, which help in the diagnosis of the atypical case and of the apparently healthy transmitter to descendants, are: (1) chronic crural ulcer in young subjects; (2) "tower skull," with vertical brow, early union of cranial sutures, and nasal retraction; (3) a relative preponderance of medulla over cortex in the long bones and broadening of tarsus and carpus, which is due, like the cranial changes, to increased medullary function; (4) microphthalmos, abnormalities of iridal pigmentation, and cataract; and (5) hypogenitalism and infantilism. The prognosis is not altogether unfavourable and longevity is fairly common, although in some families the mortality in infancy from the disease is very high. In the mild cases the author has found arsenic and blood transfusions of use, but liver treatment is ineffective and iron has been reported as dangerous. Irradiation of the spleen induces haemolytic crises, and should be abandoned. Splenectomy leads to lasting improvement, although slight recurrences, and occasionally slight icterus without anaemia, may persist: the mortality in Gänsslen's forty cases was 3.4 per cent. Splenectomy is best carried out between crises, and there is less danger of embolus and thrombosis if it is done during childhood. It may be preceded by transfusions and injections of adrenaline, which diminish the splenic tumour. A specially rapid skeletal growth often follows splenectomy, and there is usually a very speedy increase in platelets and a diminution of reticulocytes. Some degree of anisomicrocytosis usually persists.

232 Immunity to Small-pox

G. A. HALLDÉN (*Hygiea*, Stockh., July 15, 1937, p. 490) has investigated the incidence of small-pox in Sweden in the families in which cases of it occurred between 1892 and 1893 and between 1900 and 1917. The limitation of his studies to such infected families was determined by the consideration that there could be no question as to exposure to infection. According to one of his tables, 89 out of 305 vaccinated persons exposed to family infection developed small-pox; vaccination had therefore proved effective in over 70 per cent. Out of the eighty-nine persons who contracted small-pox 70.7 per cent. suffered from it in only a mild form. After giving other similar statistics the author comes to the conclusion that vaccination early in childhood remains effective in from 65 to 70 per cent. of a community of all ages exposed to small-pox, and in those who do contract it it usually takes a comparatively mild form. The author considers that the English and German small-pox committees at the end of the last century gave too short a term for the duration of the immunity conferred by vaccination when they put it at only ten years. Holmgren and Lindström showed as recently as 1937 that effective immunity to small-pox is still enjoyed by more than 40 per cent. of the persons whose vaccination in childhood dates back some five decades.

233 Pleurisy in Artificial Pneumothorax

G. TORELLI (*Ann. Ist. Carlo Forlanini*, April, 1937, p. 13) divides the cases of pleurisy he is reviewing into lamellar pleurisy and pachypleuritis with or without adhesions, and he gives an account of a hundred cases of each. In lamellar pleurisy the thickening was less than 2 mm.; pachypleuritis did not commonly follow, and the thickening in 20 per cent. of cases persisted for at least a year. Effusion occurred in lamellar pleurisy, pachypleuritis, and adherent pachypleuritis in 73, 85, and 95 per cent. of cases respectively. Pachypleuritis always affected the parietal, sometimes the visceral pleura, and in the majority of cases the whole parietal pleura from base to apex. Adhesions usually began at the base during the process of resorption of an effusion—hence the importance, during pneumothorax treatment, of the early evacuation of pleuritic fluid—but Torelli only saw total obliteration of the pleural cavity by adhesions in 5 per cent. of cases of adherent pachypleuritis. Although hemithoracic retraction with scoliosis and the classical signs described by Laennec may cause the presence of adhesive pachypleuritis to be suspected, the diagnosis is essentially radiological. In about 15 per cent. of cases Torelli found an "opaque pneumothorax": other screen signs which were common but not constant were rectilinear, arcuate, or bayonet-shaped tracheal displacement and dislocation of the oesophagus and heart. Some degree of diaphragmatic elevation was always present.

Surgery

234 Renal Haemangiomata

N. DALAKOPOULOS (*Z. Urol.*, 1937, **37**, 7, 458) reports forty-one cases of renal haemangiomata recorded in the literature, and describes one case of his own in which the haemangioma occurred in the upper two-thirds of the kidney. Histologically the tissue was rich in cells containing chromatin nuclei. In between the cells, which were surrounded by small cavities partially filled with blood, collagen fibrils were seen; mitosis was rare. In some places larger cavities also partially filled with blood were seen. The kidney was removed and the patient was discharged as cured. Renal haemangiomata are benign tumours, and resemble telangiectases of the skin and cavernous haemangiomata of the liver. Haematuria is the main symptom, and usually occurs suddenly, but may last for some time. Coagulation of the blood may produce typical renal colic. Symptoms lasted in one recorded case for twenty years, in another operative intervention was required after three days. Quiescent periods of variable duration may occur. A renal tumour is but rarely

palpable, and slight degrees of trauma may produce haematuria. An accurate diagnosis is impossible, but a pyelogram may give rise to suspicion of tumour formation. Haemangiomata are situated near the renal papillae in 35 per cent. of cases, and in 65 per cent. they occur either at the upper pole (25 per cent.) or in other parts of the kidney. Complications are rare, and there is no tendency to malignant degeneration. Nephrectomy is the treatment of choice, though resection of one of the renal papillae has been recorded six times in the literature. Decapsulation and other attempts to stop bleeding are only of temporary value.

235 Ulcerative Ileitis

F. LANDOIS (*Zbl. Chir.*, July 17, 1937, p. 1690) describes one case of ulcerative ileitis. He operated on a girl, aged 21, following a diagnosis of acute appendicitis. He found that the appendix was healthy, but that a piece of small intestine near the caecum, about 40 cm. long, was inflamed and covered with a fibrinous exudate. It was oedematous and cyanosed. The patient's condition deteriorated after closure of the incision, and the abdomen was therefore reopened and the inflamed bowel resected. Landois points out that although this condition is rare it is a well-defined clinical and pathological entity occurring only in the lowest portion of the ileum. The aetiology is quite unknown. Usually conservative measures result in cure, and the author believes that his case, which required operation, is an exception.

236 Varying Sensitivity to Pain

A. JORES and J. FREES (*Disch. med. Wschr.*, June 18, 1937, p. 962) have investigated the fluctuations throughout the day of the capacity of the body to feel pain by studying the effects of an electrical current of different strengths on the teeth. Between the hours of 8 a.m. and 8 p.m. they tested seventeen persons in this manner, as well as three persons at other hours. All twenty reacted in the same way, their pain chart showing that their sensitiveness to pain increased slowly during the day until the peak was reached about 6 o'clock. After that there was a fairly rapid decrease followed by a comparatively uniform level of sensitiveness during the night. Since the sense of pain is a central phenomenon, the authors are inclined to draw general conclusions from these observations on the teeth, and to apply them to other parts of the body. The clinical observation that patients find their aches and pains worst at night is confirmed by these experiments on the teeth, and the authors suggest that their observations indicate the desirability of carrying out all painful operations early in the morning instead of late in the afternoon. In their review of the fluctuations throughout the twenty-four hours in certain phenomena concerned with the body, the authors note that spasmodic contractions of the unstriated muscles, with resultant biliary and renal colic, occur most often during the night or the evening, that infants suffering from nutritional disturbances tend to die oftener in the early morning than at any other time, and that cases of sudden death from status lymphaticus and from spasm of the pylorus are most common between the hours of 5 a.m. and 6 a.m.

237 Bony and Cartilaginous Breast Tumours

According to M. RASO (*Pathologica*, June 15, 1937, p. 229) sarcomata probably do not account for more than 6 per cent. of breast tumours, or 3 per cent. if deduction is made in the case of cystosarcomata which take a clinically benign course. About 1 per cent. occur in males. A large majority are mixed tumours, and probably over 50 per cent. are secondary to fibro-adenoma. A case is described of a rapidly lethal chondrosarcoma, with an early subcutaneous metastasis in the thigh, in a woman aged 45. Numerous giant cells were present, as well as calcareous deposits and spaces resembling Hunterian canals. She had previously had a fibro-adenoma. The literature contains descriptions of seventy-four cases of mammary tumour with cartilage or osteoid tissue, or both, three of which were in males, and they nearly all occurred in the fifth and sixth decennia. Although ulceration is rare it presents no special clinical characteristics, except that axillary lymphoglandular metastases are not often found in sarcomata. About two-fifths of the tumours contained sarcomatous zones, about one-third carcinomatous, and some both; but the *majority* were benign tumours. Cartilage and bone, or both, were present in the metastases. Mammary tumours containing cartilage or bone may be mixed-type (teratomatous) tumours, and they may arise in mesenchymal developmental detachments of primitive rib or clavicular tissue, but are due in most cases to connective-tissue metaplasia. The presence of giant cells in sarcoma of the breast is distinctly uncommon; in Raso's case they were abundant near the cartilaginous and osteoid zones, and resembled osteoclasts.

Therapeutics

238 Protection Against Ultra-violet Irradiation

E. URBACH and F. KRAL (*Klin. Wschr.*, July 3, 1937, p. 960) have been able to prove experimentally that the skin reaction to ultra-violet irradiation can be prevented by rubbing the skin with ol. bergamottae beforehand, and by giving the patient a sufficient dose of vitamin C by mouth, rectum, or intravenous injection. The protection is temporary, and is only effective against the short waves of a mercury-vapour lamp and not against an arc lamp. The authors believe that it is produced by a chemical combination between the ol. bergamottae and the vitamin C. Only the crude ol. bergamottae is of value: no other essential oil seems to possess this protective quality.

239 Treatment of Rheumatism

E. SCHLIEPHAKE (*Zbl. inn. Med.*, July 10, 1937, p. 577) is of the opinion that all sources of focal infection must be removed before any other treatment of rheumatic conditions is instituted. The teeth, tonsils, gall-bladder, and the urogenital system may require attention, after which short-wave therapy may be started. The author does not advocate temperatures higher than 38° C.: more treatments are required than when higher temperatures are used, but improvement is more lasting. The condition may temporarily become worse and improvement only begin at the end of the course. The author had good results in 80 per cent. of cases, usually of chronic conditions in patients who had previously received various treatments without result. His criterion of improvement is restoration of function and relief of pain. Anatomical changes could not be influenced. About one-third of his patients were treated with short-wave therapy alone, but the author believes that if medical measures are added treatment is less drastic and is shorter, and for this purpose he uses gold preparations, salicylates, and atophan. A diet poor in carbohydrates is also given for five days after the temperature has become normal.

240 H. SEEL (*Fortschr. Therap.*, July, 1937, p. 391) points out that in spite of the advances in the study of rheumatism and in the increase of therapeutic adjuvants the place of the salicylates is still recognized. They are of value (1) because of their bactericidal, antiseptic, and desensitizing properties, (2) because of their central analgesic action and their ability to inhibit inflammation, (3) because they increase metabolism and lower temperature, and (4) because they can be absorbed locally and stored in the tissues. When applied locally they induce hyperaemia by enlarging the lumen of the capillaries, by their absorption and storage in the diseased tissue, by their local analgesic action, and by changing the reaction of diseased

tissue. The pharmacological action of salicylates on the rheumatic organism is not yet clear, however. In afebrile local conditions the inunction of salicylate derivatives is of value. In febrile affections, especially of the joints, oral and cutaneous therapy is indicated. Local inunction is contraindicated when heat in the form of fomentations or diathermy is applied, because physical hyperthermia in combination with chemical hyperthermia often results in local burns. In certain severe cases such a reaction may be made use of in order to increase the effect of salicylates.

Ophthalmology

241 Indirect Illumination of the Cornea

F. TERRIEN (*Arch. Ophthal.*, Paris, June, 1937, p. 501) says that one of the most useful applications of the slit-lamp is in the discovery of fine keratic precipitates in iridocyclitis or low-grade choroiditis. The slit-lamp shows up all but the finest precipitates, which can only be seen by the ocular transilluminator, which instrument has not hitherto been used in examining the anterior segment of the eye. The transilluminator is applied perpendicularly to the periphery of the cornea, which has been anaesthetized with a drug that does not alter the epithelium, and thus does not obscure the view. The light is reflected from the iris and throws up the outline of the finest precipitates sharply. Its greatest value is in the diagnosis of secondary glaucoma, which is often missed when due to low-grade iridocyclitis, and in detecting vascular "ghosts" in the interstitial layers. The instrument has the added advantage of being portable.

242 Prognosis of Papilloedema

G. HOLMES (*Brit. J. Ophthal.*, July, 1937, p. 337) discusses papilloedema due to raised intracranial pressure. The oedema of the nerve head for a time causes little structural or functional disturbance, and relief by operation will prevent the overgrowth of interstitial tissue in the nerve head which leads to blindness. Operation is often contraindicated by the impossibility of completely removing the tumour, by the shortening of the expectation of life, or by the considerable physical disablement or mortality of the operation, or by the absence of localizing signs. Papilloedema does not always cause disturbance of vision, nor even when it is long-standing does it invariably lead to blindness. It may thus be non-progressive and may subside without surgical intervention. Operation is called for in cases in which there is rapid development of papilloedema or intense congestion of the veins with haemorrhages, or when a macular fan or soft exudate on the disk appears, or there is a reduction in calibre of the arteries, or white lines are seen along the vessels, or where there is greying of the disk and reduction in vision and fields, and when temporary amaurosis with highly swollen disks is present. Operation results in subsidence of papilloedema and an improvement of slightly impaired vision and fields. The vision rarely fails after operation, particularly with a posterior fossa tumour and in the absence of any preoperative warning.

243 Dimethyl Sulphate Poisoning

S. DE GRÓSZ (*Amer. J. Ophthal.*, July, 1937, p. 700) describes the symptoms which may arise in chemical factories or after exposure to poison gas, and attributes them to the splitting off of the acid radical in the tissues. This occurs most readily on moist mucous surfaces, and when present in the eye results after a latent period of from six to eight hours in swollen lids, photophobia, lachrymation, blepharospasm, conjunctivitis, corneal roughening and scarring, iritis, and temporary field contraction and pallor of the disk. The signs are identical with those found in the late stages of mustard-gas poisoning. The sensitivity of the conjunctiva to strong light, wind, dust, and smoke persists long after the symptoms have subsided. The prognosis must therefore be guarded. Adequate douching with sodium bicarbonate, followed by the application of an alkaline ointment and the usual treatment for corneal lesions, is advised.

244 Loewi's Sign

L. HUBERT (*Arch. Ophthal.*, Chicago, June, 1937, p. 1076) confirms the work of Loewi, who said that epinephrine only dilates the pupils when the sympathetic system is hyperirritable. If the dilator of the iris and the other smooth muscles of the eye are cut off from the superior cervical ganglion, epinephrine will cause dilatation, elevation of the lid, and slight exophthalmos. This helps in localizing the lesion in cases of partial or complete Horner's syndrome. Irritation of the sympathetic fibres in ear disease is manifested, and, since simple primary glaucoma is attended by irritation of the sympathetic, susceptibility to adrenaline may be present long before any signs of glaucoma show themselves. A similar reaction is found in Graves's disease and in diabetes.

245 Quinine in Ophthalmology

J. W. ROBINSON (*New Orleans med. surg. J.*, July, 1937, p. 30) states that quinine may be used with success in ophthalmology on account of its astringent, bactericidal, and anaesthetic properties, and because it inhibits scar-tissue formation. It may be used either in the form of a 2 to 4 per cent. quinine bisulphate ointment or in a 2 per cent. solution. The bisulphate is fairly soluble in water and is less acid and less irritating to the eye than are other salts. Robinson has used it with success in cases of interstitial keratitis, trachoma, old and recent corneal opacities, vernal catarrh, and phlyctenular conjunctivitis. He also recommends a 1/2 to 2 per cent. solution of optochin (ethyl-hydroxycupreine), which is one of a number of alkaloids formed from the replacement of one of the two chemical rings composing quinine by an alkyl group, and which resembles quinine but is less active. It is a weaker protoplasmic poison, but is bactericidal in the presence of protein, and is antiseptic and anaesthetic. It is especially toxic to all types of pneumococci, streptococci, and staphylococci, and is of value in the treatment of conditions due to the Koch-Weeks and the Pfeiffer bacillus, and in some virus infections causing catarrhal conjunctivitis. Both quinine and optochin can be used in conjunction with mercury and the iodides.

246 Exophthalmos

R. DORÉ (*Union méd. Can.*, July, 1937, p. 731) describes the case of a woman, aged 47, who was sent to him with a diagnosis of exophthalmic goitre. For the past three months she had suffered from nervousness, insomnia, palpitations, anorexia, polyuria, and loss of weight. Clinically, marked exophthalmos was present: a mitral murmur was heard; the pulse was slow and regular: a trace of albumin was found in the urine, but there was no evidence of hyperthyroidism. The patient suffered from overstimulation of the sympathetic nervous system. Doré points out that exophthalmos may be present in conditions other than Graves's disease. It may be found in the presence of excessive fatty tissue in the orbit, in the presence of dilated veins behind the eyeball, after experimental production of venous thrombosis, and in the dog after experimental excitation of the cervical sympathetic or after the injection of adrenaline or anterior pituitary extract. Some authors report that this condition is due to contraction of Müller's muscle, and the appearance of exophthalmos has been recorded in a thyroidectomized patient who later became myxoedematous. According to the author, while the pathology is obscure, overstimulation of the sympathetic nervous system seems to be the most common cause.

Obstetrics and Gynaecology

247 Reconstruction of the Female Urethra

C. COLOMBINO (*Ann. Ostet. Ginec.*, May, 1937, p. 567) has had good results in reconstruction of the female urethra from plastic operations, using flaps from the neighbouring parts of the vestibule, vaginal wall, and labia minora, and also by creating a new sphincter, according to Martius's technique, from the bulbo-cavernosus or ischio-cavernosus muscles. Greater difficulties are encountered in cases in which plastic reconstruction is impossible on account of extensive scarring due to obstetric trauma or previous unsuccessful operations for fistula. Here distant postero-lateral vaginal wall grafts may be used, the neck of the bladder may be transferred to a subpubic site, or a subpubic tunnel towards the bladder may be kept open until epithelialized. Colombino thinks, however, that it is more rational to effect a vesico-vaginal interposition of the uterus, which is strongly recommended by Frank, and has been done successfully by several German surgeons. In the two cases here described of total post-obstetric destruction of the urethra, this operation was successful. In the first, nocturnal continence was regained completely; in the second, in which a suprapubic cystotomy had been maintained after the operation, complete control followed in spite of the lack of a muscular sphincter. Permanent fixation of the uterus to the ischio-pubic rami is essential, and after operation special care must be taken of the sound which has been placed in the bladder. The operation must of course be combined in young patients with a tubal sterilization, but Colombino remarks that there is abundant justification for this when other surgical attempts to relieve a most distressing condition have failed.

248 Hyperemesis Gravidarum

J. VORON and H. PIGEAUD (*Gynéc. et Obstét.*, June, 1937, p. 401) classify admissions to hospital for this condition into three groups: (1) a majority of patients whose vomiting was not originally serious, and who at once respond to hospitalization; (2) grave cases of hyperemesis which are sent sufficiently early by the medical attendant for treatment at a time when the patients still possess adequate protein, fat, and carbohydrate reserves; and (3) advanced, serious cases with little or no metabolic reserves. In both the second and third groups the initial treatment is absolute isolation, psychotherapy in which the personalities of the physician and nurses are of great importance, absolute starvation for twenty-four hours, exhibition of salines subcutaneously and rectally, and the free addition of chloral hydrate to the rectal infusion. In the second group neurovegetative imbalance, a rapidly progressing condition of dehydration, and bilious vomiting are conditions which call for special therapeutic measures. Neurovegetative disturbances demand detailed consideration and are not susceptible to a routine treatment. Sympathicotonics, with tachycardia, epigastric pain, facial vasomotor reactions, brilliant eyes, and a negative oculo-cardiac reflex, require eserine. Vagotonics, with slow pulse, sialorrhoea, and a positive oculo-cardiac reflex, should be given belladonna. Amphotonics are given eserine and belladonna, also ergotamine tartrate; and in cases in which the blood pressure is below 100 mm. (systolic) adrenaline injections are added to other treatments. For dehydration hypertonic saline-serum injections are given intravenously. Abundant bilious vomiting calls for the daily introduction of a duodenal tube, through which 33 per cent. magnesium sulphate solution as well as foodstuffs may be introduced. Even in the third class of patients it is exceptional to see one in whom abortion should at once be induced, but there are rare cases in which medical treatment is ineffective. Signs tending to justify induction are a high increasing Maillard coefficient and a declining alkali reserve.

Pathology

249 Haemoclasic Reaction

U. FOGLIANI (*Policlinico*, Sez. Chir., June 15, 1937, p. 292) states that in 1928 Citelli and Piazza described a reaction characteristic of malignant growths caused by the intravenous injection of neoplasic extracts and consisting of a true haemoclastic crisis—namely, leucopenia, diminution in the platelet count, hypotension, fibrolysis, diminution of the index of refraction of the serum, and an inversion of the leucocyte function. Fogliani records his observations on this method in fifty cases and fifteen controls. He found positive results in 62 per cent. of the morbid growths and 35.7 per cent. of the controls, consisting of healthy persons or those suffering from other diseases. Similar results were obtained by Bona (70 per cent.), Gay (64.8 per cent.), Bossa (63 per cent.), and Rotolo (62 per cent.) with the reaction in cases of malignant growths. The relatives of patients suffering from malignant growths and presenting a positive reaction were also positive in eight out of nine cases examined.

250 Wright's Reaction

A. VIGOVSKY and V. IGNATOVA (*Therap. Arch.*, Moscow, 1937, **15**, 1, p. 176) describe their experience with Wright's reaction in 300 cases of brucellosis, and compare these results with those obtained from the Widal and Weil-Felix reactions. The proportion of non-specific Wright's reactions was very small. A positive Wright's reaction has no absolute diagnostic value, but its value is vastly superior to that of the Widal and the Weil-Felix.

251 Sternal Puncture

S. GREIF (*Med. Welt*, June 19, 1937, p. 847) advises sternal puncture by means of a special needle passed through the anaesthetized skin into the sternum at the level of the second or third rib; 0.1 c.cm. of marrow is then withdrawn by a syringe and placed in a watch-glass for examination. Sternal puncture is safe and painless provided anaesthesia is complete, and the special needle prevents a passage through the posterior cortex into the mediastinum. The external table of the sternum is rarely too thick, and there are hardly ever osteosclerotic processes to prevent the marrow from being extracted. The author advocates the use of the first and smallest possible drop of marrow for quantitative estimation. He found that from 45 to 150,000 cells are found in normal marrow. The difference in cell content in marrow taken from the same place at different times is slight, but is great when obtained from different levels in the sternum. In pernicious anaemia megalocytes, megaloblasts, and promegaloblasts are found in the sternal marrow, and in secondary anaemia there is a proliferation of normoblasts. In achylic chloranaemia the marrow is rich in cells, and there is hyperplasia of the erythropoietic system and especially an increase of erythroblasts and macroblasts. In haemolytic icterus normoblasts are increased. In leukaemias all leucocytes are increased; in aleukaemic myelosis the myelocytes are increased; in agranulocytosis leucocytes and myelocytes are absent, but lymphocytes and reticulocytes are increased in fatal cases; in milder cases myelocytes and reticulocytes are increased; in cases with rapid remissions the myelocytic elements are increased; the segmented elements are decreased; in mononucleosis there is no change in the bone marrow. When myeloma is suspected sternal puncture is the diagnostic method of choice. In cases of secondary bone tumours puncture at the site of maximum pain is useful. A large-cell type occurs in adeno-carcinoma and a small-cell type in simple carcinoma. Aleukaemic conditions and myelomata can be diagnosed by sternal puncture alone. This method is an important aid to the prognosis of cases of agranulocytosis, secondary anaemia, and pernicious anaemia.

The

CONSTIPATED CHILD

Agarol simplifies the treatment of constipation by making it pleasant; children not only take Agarol with the greatest of ease but actually enjoy it.

This palatable emulsion of mineral oil and agar-agar with phenolphthalein is the ideal treatment for constipation in children. It is gentle in action and furnishes the natural stimulus to a comfortable and normal peristalsis. Its capacity for lubricating the bowel, softening the faecal mass and easing its passage to the rectum and final expulsion, is unsurpassed.

Further advantages of Agarol are that it is not habit-forming and, by mixing freely with the intestinal contents, it makes the occurrence of seepage extremely improbable.

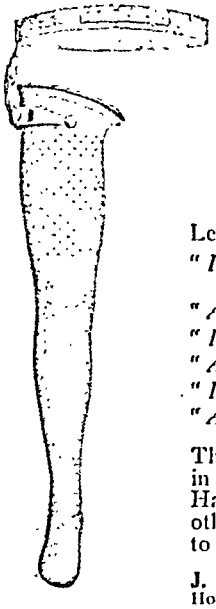
AGAROL

BRAND COMPOUND

Agarol is not advertised to the public. Supplied in 4½ oz., 7½ oz. and 17 oz. bottles.

Trial supplies to members of the Medical Profession on request.

WILLIAM R. WARNER & CO. LTD., POWER ROAD, CHISWICK, LONDON, W.4.



DINNEFORD'S
MAGNESIA

Now obtainable in TABLETS as well as the original Pure Fluid

Made only by DINNEFORD & CO. LTD. 12 CLIPSTONE ST. LONDON, W 1

"Solvitur Ambulando"

The great advances in recent years in prostheses for the lower extremities are exhaustively described and illustrated in a 72-page book under the above title.

Copies gratis to the Medical Profession on application.

Leading members of the Profession write:—

"I congratulate you on this interesting, instructive and artistic production. I consider it to be a very great addition to my library."—M.B., Ch.B., F.R.C.S.
"A very excellent brochure on artificial limbs."—M.S., F.R.C.S.
"It will prove most useful for reference."—M.D., LL.D., F.R.C.S.
"A most exquisite production and I am glad to have it."—M.S., M.D., F.R.C.S.
"I congratulate your firm on the excellence of this book."—M.A., Ch.M., M.B., F.R.C.S.
"A delightfully produced book"—K.C.M.G., M.B., B.S., F.R.C.S.

This book is the result of practical experience gained in rehabilitating over **100,000 amputees** by the Hanger establishment. Many times larger than any other limb makers in the world. It is devoted solely to making and fitting artificial limbs alone.

ANTERIOR-POSTERIOR PRESSURE FOR THE MOST SATISFACTORY SUPPORT

Effective support without constriction is made possible by the anterior-posterior pressure given by the Curtis Abdominal Support No. 1. This Support, one of over 100 abdominal appliances made by Curtis, gives steady, permanent support where it is most needed. Yet it is extremely light in weight and very comfortable in wear, giving perfect freedom to the hips. Medical Authorities throughout the world approve the Curtis Abdominal Support No. 1, and prescribe it for all cases where support upward and backwards of the lower abdomen is essential.

CURTIS

ABDOMINAL SUPPORT No1

Specialists in Abdominal Appliances.

Sole makers of

HEWLETT'S
ANTISEPTIC CREAM

An emollient healing cream for BLEPHARITIS, ACNE, ECZEMA, and all abrasions and irritation of the Skin.

Its soothing and healing properties are most marked.

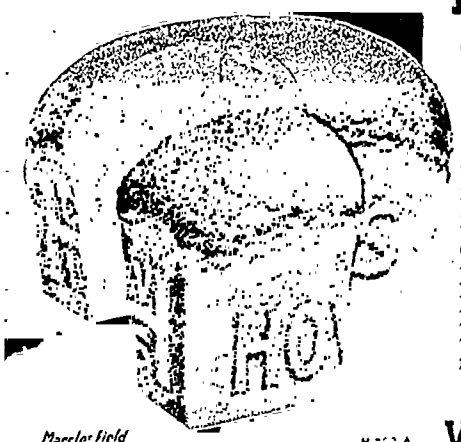
In enamelled collapsible tubes or 1-oz. pots, labelled only "The ointment to be used as directed."

In bulk, 5-oz., 10-oz., 22-oz., 40-oz., 4½-lb., and 7½-lb. pots.

INTRODUCED AND PREPARED ONLY BY

C. J. HEWLETT & SON, Ltd., 35 to 42, Charlotte Street, London, E.C.2

NEO-MONSOL
GERMICIDE

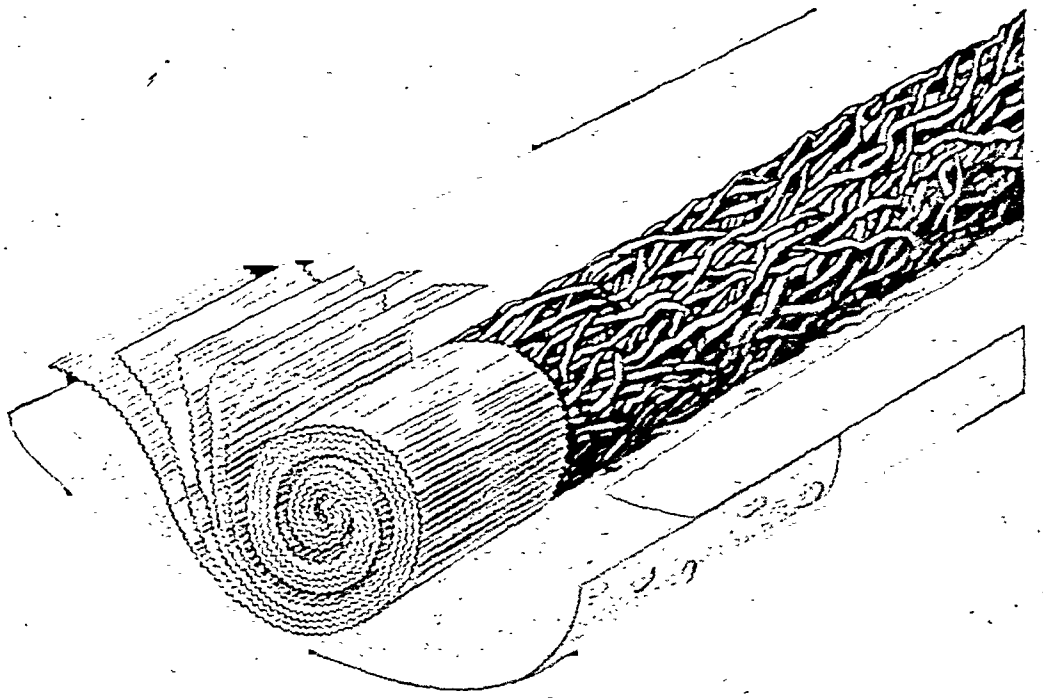


FOR SAFE ANTISEPSIS:

Six times stronger than pure Carbolic Acid

NON-TOXIC and NON-STAINING.

Samples and data from:—



MONSOL LTD., VINCENT HOUSE, VINCENT SQUARE, LONDON, S.W.1

TWENTY-FIVE per cent. of the flour from which the HOVIS loaf is produced is wheat germ

Science advocates the use of germ-bread as a factor in promoting nutrition. That is why HOVIS figures so prominently upon the dietary when the question of food value must be studied. In white bread, the wheat-germ is practically non-existent. This vitalising source of protein, fats and phosphates abounds in HOVIS. In fact, twenty-five per cent of the flour from which the HOVIS loaf is produced, is WHEAT-GERM. Apart from its low starch-content, HOVIS is practically free from bran and indigestible cellulose. This factor makes HOVIS supreme for easy digestibility and assimilation.

VITAMIN 'B' CONTENT: HOVIS 2,600 WHOLEMEAL 1,450 WHITE BREAD 200

Why the filter tip?

In every "du Maurier" cigarette you will find the filter tip. It is a five-layer protection—three layers of pure white vegetable tissue alternating with two of cellulose fibre. No irritant that might harm a sensitive throat can get through that. No stray "bits" can worry the throat. But there's no stopping the clean flavour of the finest Virginia tobacco.

du MAURIER

the perfect cigarette with the exclusive filter tip

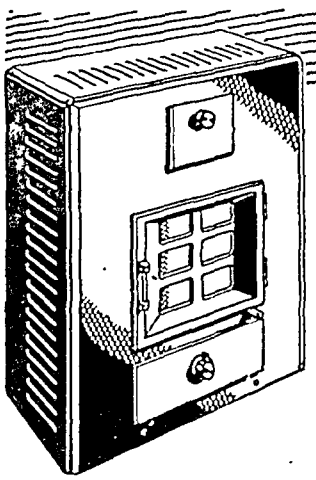
ECZEMA

Relief and cure with Peat ointment.

Because eczema generally brings pain and itching, any local dressing should attempt soothing as well as healing. And this is the great virtue of Sphagnol peat ointment — that from its first touch, it gives coolness and comfort to tender skin.



Many doctors find Sphagnol so successful that they are prompted to write about it. Here is an extract from one of the letters we have received:

"Thank you for the ointment. I have tried it on an incipient case of local eczematous trouble and found it to give great relief and to arrest the manifestation." Signed (Dr.) R. L.

Test Sphagnol personally. On receipt of a postcard we shall be pleased to send you a sufficient supply.

Sphagnol

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, and X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate, a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. *There is trout-fishing in the park.*

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton), who can be seen in London by appointment.

THE RESIDENTIAL TREATMENT OF ALCOHOLIC & DRUG ADDICTION

RENDLESHAM HALL

(Postal Address) — **WOODBRIDGE, SUFFOLK**

RENDLESHAM HALL—SOUTH VIEW

Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

Rendlesham Hall has 45 bedrooms and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated booklet giving particulars as to terms, etc., can be had on application to the

RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: WICKHAM MARKET 16. *(Toll Call from London.)*

Proprietors: The Norwood Sanatorium, Limited.

RUTHIN CASTLE, NORTH WALES

The fees are from 15 guineas a week. They include medical attendance, all scientific investigations that may be needed, such as analyses, bacteriological cultures, the ordinary *x*-ray examinations, and electrocardiograph readings; all treatment that may be prescribed such as special diets, insulin, artificial sunlight, electrical treatment, baths, massage, nursing; medicines or vaccines, board and lodging.

The only extra charge is that for a complete alimentary *x*-ray examination, or for *x*-ray therapy.

All the usual forms of treatment are given at Ruthin Castle. The climate is mild. The annual rainfall is 30.5 inches, that is, less than the average for England. There is central heating throughout.

Address—THE SECRETARY, Ruthin Castle, North Wales. *Telegrams*—Castle, Ruthin. *Telephone*—Ruthin 66

PISTANY SPA MUD

for HOME and HOSPITAL TREATMENT of persistent ***RHEUMATIC*** *disorders*

Different from ordinary heat therapy.

Why? Simultaneously with the physiological responses of the body to heat, reactions are caused specifically by this hot sulphurous, radio-active "living" mud. A detailed account of the analytical, biological, and clinical evidence appears in the September, "British Journal of Physical Medicine."

How? It is easy and clean to apply. The hot mud is wrapped in cellophane in which a window is cut to expose the mud surface to be laid on the skin. This method entirely meets the conditions prevailing in clinics or homes, and costs very little to apply.

FULL INFORMATION FROM

PISTANY AGENCY LTD., 310, Regent Street, London, W.1.

Please state when enquiring whether introducing treatment personally or prescribing treatment for patients

TREFRIW (SULPHUR-IRON) WELLS

THE SPA OF OUTSTANDING MERIT

1. These unique waters are of exceptional merit. With other properties they contain Iron as FERROUS-SULPHATE, and in such concentration that the maximum prescribed dose is only ONE OUNCE.
2. Wonderfully efficacious for all forms of rheumatic disease. Many very remarkable results are obtained in severe and chronic rheumatism and rheumatoid-arthritis—even bedridden cases of long standing—from the home treatment alone.
3. A most important feature of this Spa is the bottling of the waters in natural Spa condition for the

VICTORIA UNIVERSITY OF MANCHESTER.

SIR HENRY ROYCE RESEARCH FELLOWSHIP.

Applications are invited for the SIR HENRY ROYCE RESEARCH FELLOWSHIP, founded under the Will of the late Sir FREDERICK HENRY ROYCE, Bart. The Fellowship, for research on *either* "THE COMMON COLD, ITS NATURE, PREVENTION, AND CURE," *or* "INFLUENZA, ITS NATURE, PREVENTION, AND CURE," is of the value of £500 per annum and will be tenable in the first instance for a period of three years.

Applicants must be graduates of a British University and must be either registered Medical Practitioners or otherwise qualified to undertake research in the subjects specified. Further particulars and forms of application may be obtained from the Registrar, The University, Manchester, 13. All applications to be made on the prescribed form must be sent to reach him not later than October 31st.

A CLINICAL DEMONSTRATION

under the direction of Mr. H. O. CLARKE, of Manchester, will be held at the ROBERT JONES AND AGNES HUNT ORTHOPAEDIC HOSPITAL, OSWESTRY, on Thursday, October 21, commencing at 3.15 p.m.

The programme will be mainly practical, and will, as far as possible, demonstrate the methods by which the Hospital treats common orthopaedic conditions, and, in particular, the use of plaster, splints, etcetera.

Medical practitioners are cordially invited.

JOHN C. MENZIES,
Secretary-Superintendent.

University College Hospital Medical School,

University Street, W.C.1.

WINTER SESSION commences Tuesday, October 5th, 1937.

Scholarships and Prizes exceeding £1,000 awarded annually, and numerous vacancies for House Appointments, also Senior Posts for Registrars, etc.

Dental School Department.

(National Dental Hospital, Great Portland Street, W.1.)

Recently reorganized and equipped on the highest standard of modern requirements.

Full particulars can be obtained on application to the Dean.

RESEARCH INTO RHEUMATIC DISEASE.

Applications are invited by the EMPIRE RHEUMATISM COUNCIL for two RESEARCH FELLOWSHIPS relative to the causation and pathology of Rheumatic Disease; particularly the chronic forms. The Fellowships are tenable for seven years and holders will be expected to give their full time to the work; salary £750 a year (inclusive of resume allowance). Laboratory facilities in London will be provided by the Council.

Applicants may suggest some particular task of research which they wish to undertake, and should state their qualifications.—Address, Secretary, Empire Rheumatism Council, 1, Mitre Court Bldgs., Temple, E.C.4. Applications close November 15th.

MANCHESTER AND SALFORD HOSPITAL FOR SKIN DISEASES.

(54 Beds. 16,500 Out-patients per annum.)

HOUSE SURGEON.

Applications are invited for the post of House Surgeon. Must be registered. The appointment is for six months. Salary at the rate of £150 per annum, with board and residence.

Applications, with copies of three testimonials, to be sent to the undersigned, 61, 63 Street, Manchester, not later than October 7th.

JOHN NALL,
Secretary.

ROYAL NAVAL DENTAL SERVICE.

Vacancies exist for DENTAL OFFICERS in the ROYAL NAVY, and applications for entry are invited from Registered Dental Surgeons.

Candidates must be British subjects of pure European descent, below 28 years of age on the day of entry and physically fit for service in any part of the world. Unmarried candidates are preferred. No examination in professional subjects will be held, but approved candidates will be required to attend at the Admiralty for physical examination and interview by a Selection Board.

Successful candidates will be appointed to Short Service Commissions and a grant of £50 towards the cost of providing the necessary uniform will be paid on entry. Vacancies in the permanent list will be filled by selection from among officers holding Short Service Commissions who desire to make the Royal Naval Dental Service their permanent career. Officers not transferred to the Permanent List will, on the termination of their Short Service Engagement after six years' service, receive a gratuity of £1,000.

The rates of Full Pay for Short Service Dental Officers are £362 per annum during the first three years and £447 per annum during the second three years. Official quarters are provided.

Candidates who have, since qualifying, held full-time appointments as House Surgeons at Dental Hospitals and Schools will be eligible for an antedate of seniority up to a maximum of six months.

Officers serving under permanent commissions are eligible for a four months' postgraduate course on full pay with allowances.

Copies of the regulations for entry of conditions of Service, including rates of pay and allowances, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of Dental Schools.

Applications for entry in *January, 1938*, must be received not later than December 1st, 1937, and for entry in April, 1938, not later than March 7th, 1938.

THE LADY CHICHESTER HOSPITAL, HOVE, FOR FUNCTIONAL NERVOUS DISEASES

(60 Beds.)

SENIOR HOUSE PHYSICIAN required. Six months' appointment at £100 per annum all found.

Also JUNIOR, at £50 per annum. Valuable experience for Diploma in Psychological Medicine.

Duties to commence immediately. Applications, with testimonials, to be sent to the Secretary, Mr. P. F. Spooner, 33, West Street, Brighton.

August 21st, 1937.

THE RADIUM INSTITUTE, *Riding House Street, London, W.1.*

Applications are invited for the post of RESIDENT MEDICAL OFFICER (MALE). Candidates must be unmarried.

The salary will be at the rate of £250 per annum, board, residence, and laundry being provided, and the appointment is for six months, commencing *immediately*.

Applications, stating age, nationality, qualifications, and experience, with copies of three recent testimonials, must be received at the Institute as soon as possible.

Canvassing, either directly or indirectly, is not permitted.

THOS. A. GARNER,
Secretary.

RADIUM BEAM THERAPY RESEARCH, at the Radium Institute, 1, Riding House Street, London, W.1.

ASSISTANT MEDICAL OFFICER, resident, salary £150, non-resident, salary £250 per annum. Six months' appointment from November 1st, 1937. Applications, stating age, qualifications and experience, with copies of three recent testimonials, to be sent to the Secretary, Radium Beam Therapy Research, not later than October 5th. The selected candidate will assist with the working of two five-gramme Radium units, and will have the opportunity of combining post graduate studies with this appointment.

ROYAL MANCHESTER CHILDREN'S HOSPITAL, PENDLEBURY.

Applications are invited for the post of Non-resident ASSISTANT MEDICAL OFFICER at the Out-patients' Department, Garside Street, Manchester. Salary at the rate of £150 per annum, and the appointment is for a period of six months as from November 8th, 1937. Candidates must be on the Medical Register.

Particulars of duties can be obtained from the Secretary. The hours of duty are from 9 a.m. till 1 p.m. or until the work of the Dispensary is finished. Patients' attendances number about 100,000 per annum.

Applications, stating age, and accompanied by copies of not more than three testimonials, to be sent to the undersigned not later than Thursday, October 7th, 1937.

Canvassing, directly or indirectly, may disqualify.

By Order,
H. HEARDMAN, *Secretary.*

COUNTY COUNCIL OF MIDDLESEX.

NORTH MIDDLESEX COUNTY HOSPITAL, EDMONTON.

JUNIOR RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited for the above appointment. Candidates must be registered Medical Practitioners who have held resident appointments in a General Hospital. The duties of the appointment will be mainly obstetrical and gynaecological. Salary £250 per annum, with board, lodging and laundry, valued at £100 per annum.

The officer appointed will work under the direction of the Medical Superintendent, and will devote his or her whole time to official duties.

The appointment (which does not carry any superannuation rights, will be subject to medical examination and is terminable by one month's notice on either side) is for a period of six months in the first instance, and may be extended for an additional six months.

Applications, stating age, qualifications, and experience, together with copies of not more than three recent testimonials, must be received by the undersigned not later than October 9th. Relationship to any member or officer of the Council must be disclosed in the application.

Application forms are not provided. Envelopes must be endorsed "Junior Assistant Medical Officer, North Middlesex County Hospital." Canvassing, directly or indirectly will be a disqualification.

C. W. RADCLIFFE, "Z,"
Clerk of the County Council.

Middlesex Guildhall, Westminster, S.W.1.
September 17th, 1937.

AMENDED ADVERTISEMENT.

CITY OF NOTTINGHAM.

APPOINTMENT OF RESIDENT MEDICAL SUPERINTENDENT OF THE CITY HOSPITAL and MEDICAL OFFICER OF THE CITY INSTITUTION.

The Nottingham City Council invite applications from duly qualified persons for the appointment of RESIDENT MEDICAL SUPERINTENDENT of the CITY HOSPITAL and MEDICAL OFFICER of the CITY INSTITUTION

Candidates must present evidence of wide clinical experience gained in medical and surgical posts, and the person appointed must be an experienced and skilled administrator. He should be of strong character, capable of directing a large staff, and of assisting the Council in developments of the hospital services

The salary will be fixed between £1,100 and £1,400 per annum, according to the qualifications and experience of the selected candidate In addition, an unfurnished house, free of rates, will be provided, this emolument being valued at £100

The person appointed will not be allowed to engage in any other form of practice, and all fees received by him will be required to be paid to the Council

The duties will be carried out under the general supervision and control of the Medical Officer of Health. The appointment will be subject to the Superannuation Scheme in force, and the successful candidate will be required to pass a medical examination.

Forms of application and further particulars as to the terms and duties of the office may be obtained from me, the undersigned, and the successful candidate will be deemed to have had notice of such duties and to have accepted such terms.

Applications, endorsed "Resident Medical Superintendent," are to be delivered at my office not later than October 11th.

Canvassing, either directly or indirectly, is prohibited, and will be deemed a disqualification.

Dated this 17th day of September, 1937.

J. E. RICHARDS,
Town Clerk.

Guildhall, Nottingham.

THE KING EDWARD VII WELSH NATIONAL MEMORIAL ASSOCIATION.

Applications are invited from duly registered medical practitioners (male, single) for the posts of ASSISTANT RESIDENT MEDICAL OFFICER (twelve months' appointment in each case) at the following institutions:

(i) SULLY HOSPITAL, Sully, Glam (300 beds for the treatment of pulmonary tuberculosis), situate between Penarth and Barry.

(ii) NORTH WALES SANATORIUM (247 beds for female pulmonary, and male, female, and children non-pulmonary cases), Denbigh, North Wales

(iii) GLAN ELY HOSPITAL (196 beds for pulmonary and surgical tuberculosis in men, women and children), Fairwater, nr. Cardiff.

Salary £200 per annum, plus maintenance.

Applications, stating age, qualifications, experience, etc., together with copies of three recent testimonials, should reach the undersigned not later than Wednesday, October 6th, 1937.

D. A. POWELL,
Principal Medical Officer.

Memorial Offices, Westgate Street, Cardiff.

COUNTY COUNCIL OF MIDDLESEX.

ASSISTANT MEDICAL OFFICER.

Applications are invited for the appointment on the pensionable staff of an Assistant Medical Officer in the Public Health and School Medical Department. Salary £600 per annum, rising after two years' service by annual increments of £30 to £750, together with out-of-pocket travelling expenses.

Applicants must be duly qualified registered medical practitioners, and should have had special experience of ante-natal work. The possession of a Degree or Diploma in Public Health will be an additional qualification.

The duties of the post are the medical inspection of school children, the supervision of treatment of minor ailments, the carrying out of work under the maternity and child welfare scheme, and such other duties as may be required by the Council.

The officer appointed will devote whole time to the duties of the post, act under the direction of the County Medical Officer of Health, and reside in such district as may be required.

The appointment, which will be subject to medical examination, will be held during the pleasure of the Council, and will be terminable by one month's notice on either side.

Applications, stating age, qualifications and experience, together with copies of not more than three recent testimonials, must be received by the undersigned not later than October 2nd. Relationship to any member or officer of the Council must be disclosed in the application. Application forms are not provided. Envelopes must be endorsed "Assistant Medical Officer 'Z.'"

Canvassing, directly or indirectly, will be a disqualification

C. W. RADCLIFFE,
Clerk of the County Council.

Middlesex Guildhall,
Westminster, S.W.1
September 8th, 1937.

ESSEX COUNTY COUNCIL.

JUNIOR ASSISTANT MEDICAL OFFICER

The County Council of the Administrative County of Essex invite applications for the appointment of Junior Assistant Medical Officer at the BLACK NOTLEY SANATORIUM, near BRAINTREE.

This Sanatorium has 300 beds for the treatment of pulmonary and non-pulmonary tuberculosis in men, women and children, and has all modern facilities for diagnosis and treatment, together with a staff of visiting Specialists.

The appointment is for a period of one year, and the salary will be at the rate of £250 per annum, together with board, lodging and laundry. The successful applicant will be required to pass a medical examination, and will be subject to the Council's Sick Pay Rules and Regulations, a copy of which will be forwarded on application

Applications in candidate's own handwriting, stating age, qualifications and experience, accompanied by copies of not more than three recent testimonials which will not be returned, should be addressed to me and delivered at the County Hall, Chelmsford, not later than 10 a.m. on Monday, October 11th, 1937.

E. S. HOLCROFT,
Clerk of the County Council.

County Hall, Chelmsford.
September 21st, 1937.

BOROUGH OF ILFORD.

APPOINTMENT OF DEPUTY MEDICAL OFFICER OF HEALTH.

Applications are invited from legally qualified Medical Practitioners, holding the Diploma of Public Health or similar qualifications, for the above appointment, at a commencing salary of £750 per annum, rising by annual increments of £25 to a maximum of £900 per annum.

Applicants must not exceed the age of 45 years, but an applicant who is an ex-Service man may deduct from his age his period of service during the Great War for the purpose of bringing himself within the above age limit.

The appointment will be subject to confirmation by the Minister of Health, to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and to the Staff Regulations of the Council. The selected applicant will be required to pass a medical examination by and to the satisfaction of the Medical Officer of Health and to enter into a service agreement. The appointment will also be subject to three months' notice on either side.

The person appointed will be required to reside within the Borough of Ilford.

Applications on the prescribed form which (together with list of duties) is obtainable from my office, must be received by me at the Town Hall, Ilford, not later than October 8th, 1937.

Canvassing, directly or indirectly, will be a disqualification.

CHARLES N ROBERTS,
Town Clerk.

Town Hall, Ilford.

LANCASHIRE COUNTY COUNCIL.

PARK HOSPITAL, DAVYHULME, NEAR MANCHESTER.

APPOINTMENT OF SENIOR RESIDENT MEDICAL OFFICER

Applications are invited from registered male Medical Practitioners for the appointment of SENIOR RESIDENT MEDICAL OFFICER at the above Hospital. Candidates must be unmarried.

Salary £350 per annum, together with the usual residential allowances.

The appointment will, in the first instance, be for a period of six months, the successful applicant being eligible for reappointment for a further period of six months at the end of that period.

The Hospital comprises 500 beds for acute cases, is fully equipped in every respect, and is recognised as a complete Training School for Nurses.

The appointment will be terminable by one month's notice on either side.

Forms of application may be obtained from the County Medical Officer of Health, Hospital and Medical Department, County Offices, Preston, to whom all applications, accompanied by copies of not more than two recent testimonials, must be forwarded so as to be received not later than Saturday, October 9th, 1937.

GEORGE ETHERTON,
Clerk of the County Council.

County Offices, Preston.
September 20th, 1937.

LANCASHIRE COUNTY COUNCIL.

PUBLIC ASSISTANCE COMMITTEE.

LAKE HOSPITAL AND DARNTON HOUSE, ASHTON-UNDER-LYNE, NEAR MANCHESTER.

APPOINTMENT OF JUNIOR RESIDENT MEDICAL OFFICER.

Applications are invited from registered medical practitioners for the appointment of Junior Resident Medical Officer at the above Hospital and Institution, comprising 300 and 525 beds respectively. The Hospital is recognized as a complete Training School for Nurses.

Candidates must be unmarried. Salary at the rate of £225 per annum, together with the usual residential emoluments.

The appointment will, in the first instance, be for a period of six months, the successful applicant being eligible for reappointment for a further period of six months at the end of that period.

Forms of application may be obtained from the County Medical Officer of Health, Public Assistance (Hospital and Medical) Department, County Offices, Preston, to whom all applications, accompanied by copies of not more than two recent testimonials, must be forwarded not later than Wednesday, October 6th, 1937.

GEORGE ETHERTON,
Clerk of the County Council.

County Offices, Preston.
September 9th, 1937.

LANCASHIRE COUNTY COUNCIL.

PUBLIC ASSISTANCE COMMITTEE.

LAKE HOSPITAL AND DARNTON HOUSE, ASHTON-UNDER-LYNE, NEAR MANCHESTER.

APPOINTMENT OF SENIOR RESIDENT MEDICAL OFFICER.

Applications are invited from Registered Medical Practitioners for the appointment of Senior Resident Medical Officer at the above Hospital and Institution, comprising 300 and 525 beds respectively.

The Hospital is recognised as a complete Training School for Nurses.

Candidates must be unmarried.

Salary at the rate of £250 per annum, together with the usual residential emoluments.

The appointment will, in the first instance, be for a period of six months, the successful applicant being eligible for reappointment for a further period of six months at the end of that period.

Forms of application may be obtained from the County Medical Officer of Health, Public Assistance (Hospital and Medical) Department, County Offices, Preston, to whom all applications, accompanied by copies of not more than two recent testimonials, must be forwarded not later than Saturday, October 9th, 1937.

GEORGE ETHERTON,
Clerk of the County Council.

County Offices, Preston.
September 21st, 1937.

THE ROYAL INFIRMARY, BRADFORD.

TWO HOUSE PHYSICIANS and FOUR HOUSE SURGEONS (MALE) wanted for November 1st. Six months' appointments.

Candidates must be single and legally qualified. Salary £150 per annum, with board, residence, and washing.

There are 345 beds and nine Resident Officers.

Applications, stating age, qualifications, and previous experience, with copies of recent testimonials, should be sent to the undersigned not later than Monday, October 4th.

H. TRUSSON, F.C.I.S.,
House Governor-Secretary.

ROYAL ARMY MEDICAL CORPS

Applications are invited from medical men for appointment to commissions in the Royal Army Medical Corps.

Candidates will, for the present, be selected for commissions without competitive examination, and will be required to present themselves in London for interview and physical examination on, or about, 21st October, 1937. They must be registered under the Medical Acts, and normally must not be over the age of 28 years.

Successful candidates will, in the first instance, be given short service commissions for five years. During the 4th year of this period they will be given the opportunity of applying for permanent commissions in either the Royal Army Medical Corps or the Indian Medical Service. Those not selected will retire on completion of five years' service with a gratuity of £1,000.

Candidates who are successful will, unless they are seconded to complete a hospital appointment, assemble at the Royal Army Medical College, London, on 1st November, 1937.

Particulars of the Conditions of Service in the Royal Army Medical Corps, pay and allowances, and forms of application, may be obtained on application, either in writing, or personally, to the Assistant Director General, Army Medical Services, The War Office, London, S.W. 1.

ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in January, 1938.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years in the first instance, which may be extended to five years at the discretion of the Admiralty.

At the end of three years' service officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000.

At the end of five years' Short Service permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Opportunities are available for officers on the permanent list to specialise, and ample provision is made for Post-Graduate study.

Copies of the regulations for entry and conditions of service, including rates of pay and allowances, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than November 22nd, 1937.

COUNTY COUNCIL OF DURHAM.

EDUCATION DEPARTMENT.

ASSISTANT SCHOOL MEDICAL OFFICERS.

The County Education Committee invite applications for the posts of TWO ASSISTANT SCHOOL MEDICAL OFFICERS, to act under the School Medical Officer in connexion with the inspection of school children, and such other duties as may be required by the Education Committee. Commencing salary £500 per annum (provided the candidates have had not less than three years' post-graduate experience), rising by annual increments of £25 to £700 per annum, together with travelling expenses according to the County Scale. The successful candidates will be required to devote their whole time to the duties of the office and reside in or near the districts to which they will be attached at places to be approved by the Education Committee. The appointments will be subject to three calendar months' notice on either side, expiring on the last day of any calendar month. Applicants must have had experience in the work of school medical inspection, and preference will be given to candidates who:

(*a*) Have had experience in the work of School Clinics;

(*b*) Have been accustomed to make special reports on Mentally Defective, Physically Defective, Epileptic and other Defective children.

The possession of a Diploma in Public Health is desirable, though not essential.

Canvassing, directly or indirectly, is prohibited and will disqualify.

A deduction of 5 per cent. will be made from the salary in accordance with the Local Government and Other Officers' Superannuation Act, 1922, which has been adopted by the Council, and the appointment will be subject to passing the County Council's medical examination in connexion therewith.

Forms of application to be returned not later than Saturday, October 9th, 1937, may be obtained from the Director of Education, Shire Hall, Durham, on receipt of stamped addressed foolscap envelope.

THOS. B. TILLEY,
Director of Education.

Shire Hall, Durham
September 16th, 1937

CITY AND COUNTY OF THE CITY OF CHESTER.

CITY HOSPITAL (288 Beds)

Applications are invited for the post of SENIOR RESIDENT MEDICAL OFFICER (Male) at the above Hospital. Applicants must have had experience in a Voluntary Hospital as a House Physician and/or experience as a Resident Medical Officer in a Municipal General Hospital. The person appointed will be responsible, under the direction of the Medical Officer of Health for the City, who is also Medical Superintendent of the Hospital, for the general medical work of the Hospital. The salary attached to the post is £400 per annum, rising by two annual increments of £25 to £450 per annum, with board, residence, and laundry.

Canvassing, either directly or indirectly, will be a disqualification.

Applications, stating age, qualifications, and previous experience, with copies of three recent testimonials, must be received by the Medical Officer of Health, Town Hall, Chester, on or before October 1st, 1937.

September 22, 1937 By Order of the Council. G. C. ANDERSON, *Secretary.*

BRISTOL GENERAL HOSPITAL.

RESIDENT SURGICAL OFFICER AND REGISTRAR (male).

The Committee invites applications for the appointment. Salary at the rate of £200 per annum (plus estimated emoluments of £200 p.a.), with board, residence, etc., provided in the Hospital. Candidates must be registered under the Medical Acts, and produce testimonials of good personal character and ability. The duties attaching to the post are chiefly surgical, but being also in part administrative, experience in this direction is therefore essential.

Applications, accompanied by copies of testimonials, three of which must preferably be given in support of the application, to be forwarded to the undersigned on or before October 5th, from whom forms of application and copies of the duties may be obtained.

The Hospital contains 273 beds, and is a School of Medicine attached to the University of Bristol.

THOMAS W. GREGG, F.C.C.S., Secretary.

HULL ROYAL INFIRMARY.

Applications are invited from registered Medical Practitioners for the following post (male):—

SECOND CASUALTY OFFICER, vacant October 5th. Salary at the rate of £150 per annum, plus board, residence, and laundry.

In addition to carrying out duties in the Casualty Department, the Officer appointed will act as House Surgeon to one of the Honorary Assistant Surgeons, and will thus obtain Ward and Theatre experience. He will be eligible for promotion to a more senior post when a vacancy occurs.

The appointment will be for a period of six months, but will be determinable at any time by one month's notice on either side.

Applications, giving particulars of age, experience, and nationality, together with copies of recent testimonials, should be addressed to the undersigned.

R. J. CARLESS, September 13th, 1937. House Governor.

BURY INFIRMARY (LANCS) (127 Beds.)

RESIDENT SURGICAL OFFICER (MALE).

Applications are invited for the above post from those holding the Fellowship of one of the Royal Colleges of Surgeons.

The appointment is for a term of one year, with provision for an extension of a further twelve months, and the successful candidate will be expected to commence duties immediately.

Salary will be paid at the rate of £400 per annum, together with board, residence and laundry.

Applications, stating age, qualifications, and nationality, together with copies of three recent testimonials, are to be addressed to the undersigned, and should be forwarded as soon as possible, endorsed "R.S.O."

H. WILKINSON, Superintendent.

DERBYSHIRE HOSPITAL FOR SICK CHILDREN. (80 Beds.)

Wanted—forthwith—RESIDENT HOUSE PHYSICIAN (LADY). Salary £130 p.a. The appointment is for six months. Applicants must be fully qualified. Applications, with three testimonials, to be sent to the undersigned.

ARTHUR N. WHISTON, Secretary.

25, St. Mary's Gate, Derby.

GREAT YARMOUTH GENERAL HOSPITAL. (72 Beds.)

Applications are invited for the post of HOUSE SURGEON (one of two appointments). Duties to commence at once.

Applicant must be male and unmarried. Salary at the rate of £140 per annum, with board, residence and laundry.

Applications, stating age and qualifications, together with copies of three recent testimonials, to be forwarded to the undersigned.

FREDK. L. GAITFIELD, Secretary.

NORTH LONSDALE HOSPITAL, BARROW-IN-FURNESS. (152 Beds.)

There will be vacancies for a Resident Surgical Officer and a RESIDENT HOUSE PHYSICIAN at this Hospital on October 15th, 1937, and applications are invited for the positions from fully qualified male Practitioners experienced in the administration of Anaesthetics. Salaries, Surgical Officer £200 and Physician £175 per annum, with board, residence and laundry. Applications, stating age, qualifications, experience and nationality, accompanied by copies only of three recent testimonials, should be sent to the Secretary on or before September 30th.

PRINCESS ALICE MEMORIAL HOSPITAL, EASTBOURNE.

(Voluntary General Hospital, 120 Beds, Two House Surgeons.)

Applications are invited for the post of RESIDENT HOUSE SURGEON (male), vacant on October 5th, 1937. Salary at the rate of £150 per annum, with board and laundry.

Applications, with copies of three recent testimonials, should be delivered to the undersigned by first post on Wednesday, September 29th, 1937.

W. RUSSELL RUDALL, September 13th, 1937. Secretary.

BRISTOL ROYAL INFIRMARY.

Applications are invited for the post of SENIOR HONORARY ANAESTHETIST. Candidates must be registered Medical Practitioners and hold a Diploma in Anaesthetics of the Conjoint Board of the Royal College of Physicians and Surgeons of England. Applications, stating age, together with copies of not more than three recent testimonials, to be sent to the undersigned on or before October 16th, 1937.

ELLIS C. SMITH, F.C.I.S., Secretary and House Governor.

F. DUDLEY HOBBS, B.A.,
Secretary.

METROPOLITAN BOROUGH OF SOUTHWARK.

LADY ASSISTANT MEDICAL OFFICER.

The Council invite applications from fully qualified medical women for the appointment of a whole time LADY ASSISTANT MEDICAL OFFICER.

Applicants must be under 45 years of age and possess the Diploma of Public Health. The following experience is essential, full details of which must be given in the application form:—

1. Special experience in the management and dietetics of infancy.

2. A postgraduate appointment in a hospital devoted to the treatment of children's diseases.

3. Special experience in ante-natal care and management of pregnancy.

Practical experience in artificial light therapy, Schick testing and immunization against diphtheria will be regarded as valuable additional qualifications.

The officer appointed will work under the direction and control of the Medical Officer of Health, and her principal duties will be in connexion with Maternity and Child Welfare services, but she must be prepared to undertake any other duties in connexion with the Public Health work of the Council when required to do so.

The salary is £500 per annum, rising by annual increments of £25 to a maximum of £700. The appointment may be determined by three months' notice on either side, and the successful candidate must pass the medical examination prescribed by the Council and be subject to the provisions of the Shoreditch and Other Metropolitan Borough Councils (Superannuation) Acts, 1922 to 1937. The appointment is also subject to the Council's Standing Orders, which provide that in the event of the marriage of any of the female staff, her appointment shall be terminated forthwith.

Forms of application may be obtained from me on sending a foolscap stamped addressed envelope to this office.

Applications on the official form, accompanied by copies of three recent testimonials, should be sent to me, endorsed "LADY ASSISTANT MEDICAL OFFICER," so as to reach this office not later than noon on Monday, October 4th, 1937.

Canvassing, either directly or indirectly, will disqualify.

D. T. GRIFFITHS,
Town Clerk.

Southwark Town Hall,
Walworth Road, S.E.17.
September 21st, 1937.

AMENDED ADVERTISEMENT.

COUNTY BOROUGH OF MERTHYR TYDFIL.

APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH and ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited from Medical Women (unmarried or widowed) under the age of forty, for the above post. The person appointed must be a registered Medical Practitioner, and registered in the Medical Register as the holder of a Diploma in Sanitary Science, Public Health, or State Medicine. Preference will be given to a candidate who:

(1) Has had at least three years' experience in the practice of her profession.

(2) Has held the appointment of Resident Medical Officer in a Maternity Department for a period of not less than six months.

(3) Has had not less than one year's continuous experience in some branch of obstetric work.

The duties will include School Medical Inspection, Supervision of Midwives, attendance at Antenatal and Infant Welfare Centres, and other Public Health duties as may from time to time be prescribed. The duties of the respective offices will be carried out under the general direction of the Medical Officer of Health.

The salary will be at the rate of £600 per annum, rising by annual increments of £25 to a maximum of £700 per annum, together with out-of-pocket travelling expenses.

Applications, together with copies of three recent testimonials, must reach the undersigned on or before October 1st, 1937.

Schedule of Terms will be forwarded on application.

Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges
No charge is made to Principals for the introduction of Locum Tenens or Assistants.

1. HOME COUNTIES.—PROSPEROUS TOWN WITHIN 20 MILES OF LONDON.—PARTNERSHIP.—A one-third share is for disposal in an old-established non-dispensing practice. Gross cash receipts for this year at the rate of £2,000 p.a. Panel of about 1,400 (increasing). Fees 3/6 to 21/-. Ample scope. Choice of houses. Premium for share £1,250, part by instalments. Ingoing partner must be experienced and accustomed to better-class work.
2. LONDON, SOUTH-WEST.—Well-established better working-class PRACTICE, averaging about £3,500 p.a., including Panel of over 2,300 patients. Very good house on rental in excellent repair with 5 bedrooms, etc., and very good professional accommodation.
3. SOUTH-WEST LONDON.—PRACTICE has been established over 40 years and has been held by vendor (who wishes to return abroad) about ten years. Gross cash receipts for last 12 months over £900, including Panel of about 350, which could be increased. Suitable house with 5 bedrooms on rental. Moderate premium for quick sale.
4. KENT COAST.—FAVOURITE SEASIDE RESORT.—PRACTICE established 40 years and now for disposal as vendor is going abroad. Gross cash receipts average £1,921 p.a., including about £550 from Panel and £235 from Clubs. Good hospital. Vendor on staff. *Scope for increase and for some* surgery. Good freehold house available with ample accommodation. Freehold £1,200. Premium 2 years' purchase.
5. DORSET COAST.—A VERY FAVOURED LOCALITY.—PRACTICE, old-established held by vendor for 10 years and only for disposal as he wishes to devote whole time to pathology. Gross cash receipts for past year about £1,127. Selected panel of 250 patients. Fees 3/6 upwards, including medicine. Visits from 5/-. Few midwifery cases at from 3 guineas. Good house in ¾-acre for disposal, freehold. Accommodation consists of consulting room, 2 reception, 5 bedrooms and 2 attics. Good garden and garage. Premium 2 years' purchase.
6. KENT.—LARGE TOWN.—P[illegible]e) established by vendor 12 years ago now Gross cash receipts are stated to be abo[illegible] of about 800 patients. Fees, advice and me[illegible]. Midwifery from 3 guineas. House situated in a pleasant and secluded garden, contains 2 large public rooms with commodious hall and staircase, 4 large bedrooms, etc. Surgery and dispensary. *Freehold for sale or might be rented. Premium* for house and practice, £2,000.
7. WEST MIDLANDS.—PLEASANT RESIDENTIAL TOWN.—PRACTICE producing about £1,600 p.a., including a selected Panel of about 560 patients. Mostly better-class and non-dispensing. Consultations 3/6 to 10/6. Visits 5/- to 1 guinea. Freehold house for disposal, contains 3 reception, 3 large and 3 smaller bedrooms with separate servant's quarters. Excellent consulting rooms, garage for 2 cars.
8. HAMPSHIRE NUCLEUS—stated to be producing now at the rate of £5 per week and to offer considerable scope for an energetic worker.
9. COAST TOWN.—Old-established, held by Vendor past 3½ years and now for disposal as he wishes to specialise. Gross earnings for year ending 31/3/37, approximately £2,183. Panel of about 770 patients producing about £425 p.a., and appointments producing about £100 p.a. Fees 3/6 and 5/- Visits from 5/-. Good house available, freehold £1,100. Accommodation consists of consulting room, 7 bedrooms, 2 reception rooms, etc. Premium 2 years' purchase or near offer.
10. LINCS.—PRACTICE, which is practically unopposed and country, was established by the vendor about 40 years ago and now for disposal owing to ill-health. The receipts for past three years have been about £540 p.a., and there is stated to be good scope for increase as practice has been neglected. Panel of about 600 patients. Suitable house available on rental at £30 p.a., with 2 reception and 4 bedrooms, garden and garage. Premium 1½ years' purchase.
11. EAST LONDON.—Old-established PRACTICE producing about £1,800 p.a. Panel of nearly 2,600 patients. Fees 2/- to 3/-. Visits from 3/-. Midwifery, 3 to 5 guineas, about 20/30 cases yearly. *Very good house on rental at* £120 p.a. Accommodation consists of surgery, waiting room, 2 reception and 4 bedrooms, 2 maids' rooms and bathroom. Garage. Premium £3,600.
12. LONDON.—Outlying Northern Suburb.—PARTNERSHIP—A one-third share is *available in a rapidly expanding Practice. Receipts for past three* years are approximately £1,924-£2,900 and £3,550. Panel of 2,354 patients. Fees 2/6 and 3/6—visits 3/6 upwards. Midwifery about 40/50 cases per annum, minimum 4½ guineas. Considerable scope for further increase. Ingoing partner must be well experienced and have held Hospital appointments, be interested in medicine and children, and, in addition, be a good anaesthetist. Short preliminary assistantship.
13. LANCS.—High-class Seaside and Residential Town.—Easily worked old-established PRACTICE for sale. Gross cash receipts about £1,100 p.a., including a panel of about 325 patients. Fees 3/6 to 10/6. Visits 5/- to 21/-. Midwifery about 12 cases p.a. Minimum 5 guineas rising to 15 guineas. Mostly non-dispensing. Low expenses. Suitable house available with consulting and waiting rooms, 2 reception, 3 bedrooms and a maid's room and box room. Large garden and garage. Leasehold for sale or would be rented. Premium 1¾ years' purchase. There is stated to be good scope for increase for an energetic man.
14. SUSSEX.—ATTRACTIVE COUNTRY DISTRICT NEAR SEA.—PARTNERSHIP.—A one-fourth share is offered (after a preliminary assistantship) in an old-established and expanding Practice. Gross cash receipts for 1936 were about £3,300 and for the past 8½ months approximately £2,700. Panel of 1,300 patients. Appointments worth over £300 p.a. Maisonette *available or Senior partner might build new house.* Premium 2 years' purchase.
